The Ends of Four Big Inflations

Thomas J. Sargent

2.1 Introduction

2

Since the middle 1960s, many Western economies have experienced persistent and growing rates of inflation. Some prominent economists and statesmen have become convinced that this inflation has a stubborn. self-sustaining momentum and that either it simply is not susceptible to cure by conventional measures of monetary and fiscal restraint or, in terms of the consequent widespread and sustained unemployment, the cost of eradicating inflation by monetary and fiscal measures would be prohibitively high. It is often claimed that there is an underlying rate of inflation which responds slowly, if at all, to restrictive monetary and fiscal measures.¹ Evidently, this underlying rate of inflation is the rate of inflation that firms and workers have come to expect will prevail in the future. There is momentum in this process because firms and workers supposedly form their expectations by extrapolating past rates of inflation into the future. If this is true, the years from the middle 1960s to the early 1980s have left firms and workers with a legacy of high expected rates of inflation which promise to respond only slowly, if at all, to restrictive monetary and fiscal policy actions. According to this view, restrictive monetary and fiscal actions in the first instance cause substantial reduc-

Thomas J. Sargent is with the Federal Reserve Bank of Minneapolis and the Department of Economics, University of Minnesota.

The views expressed herein are solely those of the author and do not necessarily represent the views of the Federal Reserve Bank of Minneapolis or the Federal Reserve System. Helpful comments on earlier drafts of this paper were made by Preston Miller, John Kennan, Peter Garber, and Gail Makinen. General conversations on the subject with Michael K. Salemi and Nell Wallace were most helpful. Gail Makinen directed the author's attention to the unemployment figures for Poland. Carl Christ of the NBER reading committee made several comments that Improved the manuscript.

tions in output and employment but have little, if any, effects in reducing the rate of inflation. For the economy of the United States, a widely cited estimate is that for every one percentage point reduction in the annual inflation rate accomplished by restrictive monetary and fiscal measures, \$220 billion of annual GNP would be lost. For the \$2,500 billion United States economy, the cost of achieving zero percent inflation would be great, indeed, according to this estimate.

An alternative "rational expectations" view denies that there is any inherent momentum in the present process of inflation.² This view maintains that firms and workers have now come to expect high rates of inflation in the future and that they strike inflationary bargains in light of these expectations.³ However, it is held that people expect high rates of inflation in the future precisely because the government's current and prospective monetary and fiscal policies warrant those expectations. Further, the current rate of inflation and people's expectations about future rates of inflation may well seem to respond slowly to isolated actions of restrictive monetary and fiscal policy that are viewed as temporary departures from what is perceived as a long-term government policy involving high average rates of government deficits and monetary expansion in the future. Thus inflation only seems to have a momentum of its own; it is actually the long-term government policy of persistently running large deficits and creating money at high rates which imparts the momentum to the inflation rate. An implication of this view is that inflation can be stopped much more quickly than advocates of the "momentum" view have indicated and that their estimates of the length of time and the costs of stopping inflation in terms of foregone output (\$220 billion of GNP for one percentage point in the inflation rate) are erroneous. This is not to say that it would be easy to eradicate inflation. On the contrary, it would require far more than a few temporary restrictive fiscal and monetary actions. It would require a change in the policy regime: there must be an abrupt change in the continuing government policy, or strategy, for setting deficits now and in the future that is sufficiently binding as to be widely believed. Economists do not now possess reliable, empirically tried and true models that can enable them to predict precisely how rapidly and with what disruption in terms of lost output and employment such a regime change will work its effects. How costly such a move would be in terms of foregone output and how long it would be in taking effect would depend partly on how resolute and evident the government's commitment was.

This paper describes several dramatic historical experiences which I believe to be consistent with the "rational expectations" view but which seem difficult to reconcile with the "momentum" model of inflation. The idea is to stand back from our current predicament and to examine the measures that successfully brought drastic inflations under control in

several European countries in the 1920s. I shall describe and interpret events in Austria, Hungary, Germany, and Poland, countries which experienced a dramatic "hyperinflation" in which, after the passage of several months, price indexes assumed astronomical proportions. The basic data to be studied are the price indexes in figures 2.1-2.4. These data are recorded in a logarithmic scale, so that they will fit on a page. For all four countries, and especially Germany, the rise in the price level was spectacular. The graphs also reveal that in each case inflation stopped abruptly rather than gradually. I shall also briefly describe events in Czechoslovakia, a country surrounded by neighbors experiencing hyperinflations, but which successfully achieved a stable currency itself. My reason for studying these episodes is that they are laboratories for the study of regime changes. Within each of Austria, Hungary, Poland, and Germany, there occurred a dramatic change in the fiscal policy regime which in each instance was associated with the end of a hyperinflation. Further, though it shared some problems with its four neighbors, Czechoslovakia deliberately adopted a relatively restrictive fiscal policy regime, with the avowed aim of maintaining the value of its currency.

While there are many differences in details among the Austrian, Hungarian, Polish, and German hyperinflations, there are some very important common features. These include the following:

i) The nature of the fiscal policy regime in effect during each of the hyperinflations. Each of the four countries persistently ran enormous budget deficits on current account.

ii) The nature of the deliberate and drastic fiscal and monetary measures taken to end the hyperinflations.

iii) The immediacy with which the price level and foreign exchanges suddenly stabilized.⁴

iv) The rapid rise in the "high-powered" money supply in the months and years after the rapid inflation had ended.

I shall assemble and interpret the facts in the light of a view about the forces which give money value and about the way the international monetary system worked in the 1920s. Before interpreting the historical facts, I now turn to a brief description of this view.

2.2 The Gold Standard

After World War I, the United States was on the gold standard. The United States government stood ready to convert a dollar into a specified amount of gold on demand. To understate things, immediately after the war, Hungary, Austria, Poland, and Germany were not on the gold standard. In practice, their currencies were largely "fiat," or unbacked. The governments of these countries resorted to the printing of new

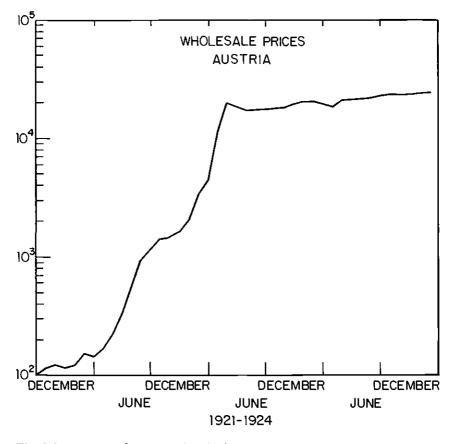

Fig. 2.1 Wholesale prices in Austria.

unbacked money to finance government deficits.⁵ This was done on such a scale that it led to a depreciation of the currencies of spectacular proportions. In the end, the German mark stabilized at 1 trillion (10^{12}) paper marks to the prewar gold mark, the Polish mark at 1.8 million paper marks to the gold zloty, the Austrian crown at 14,400 paper crowns to the prewar Austro-Hungarian crown, and the Hungarian krone at 14,500 paper crowns to the prewar Austro-Hungarian crown.⁶

This paper focuses on the deliberate changes in policy that each of Hungary, Austria, Poland, and Germany made to end its hyperinflation, and the deliberate choice of policy that Czechoslovakia made to avoid inflation in the first place. The hyperinflations were each ended by restoring or virtually restoring convertibility to the dollar or equivalently to gold. For this reason it is good to keep in mind the nature of the restrictions that adherence to the gold standard imposed on a government. Under the gold standard, a government issued demand notes and

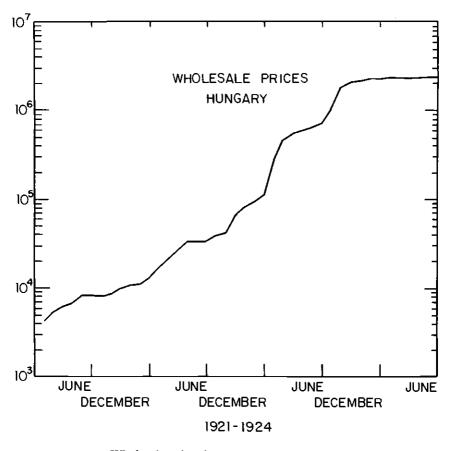

Fig. 2.2 Wholesale prices in Hungary.

longer-term debt which it promised to convert into gold under certain specified conditions, i.e. on demand, for notes. Presumably, people were willing to hold these claims at full value if the government's promise to pay were judged to be good. The government's promise to pay was "backed" only partially by its holding of gold reserves. More important in practice, since usually a government did not hold 100% reserves of gold, a government's notes and debts were backed by the commitment of the government to levy taxes in sufficient amounts, given its expenditures, to make good on its debt. In effect, the notes were backed by the government's pursuit of an appropriate budget policy. During the 1920s, John Maynard Keynes emphasized that the size of a government's gold reserve was not the determinant of whether it could successfully maintain convertibility with gold: its fiscal policy was.⁷ According to this view, what mattered was not the current government deficit but the present value of current and prospective future government deficits. The government was

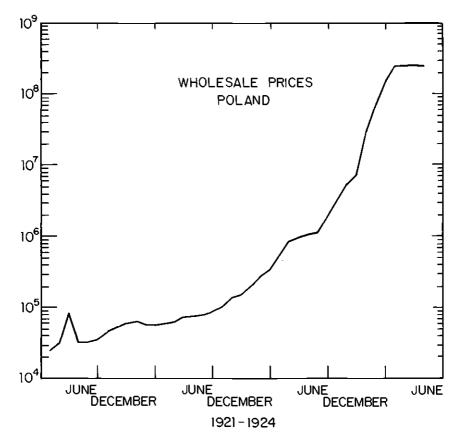

Fig. 2.3 Wholesale prices in Poland.

like a firm whose prospective receipts were its future tax collections. The value of the government's debt was, to a first approximation, equal to the present value of current and future government surpluses. So under a gold standard, a government must honor its debts and could not engage in inflationary finance. In order to assign a value to the government's debt, it was necessary to have a view about the fiscal policy regime in effect, that is, the rule determining the government deficit as a function of the state of the economy now and in the future. The public's perception of the fiscal regime influenced the value of government debt through private agents' expectations about the present value of the revenue streams backing that debt.⁸ It will be worthwhile to keep this view of the gold standard in mind as we turn to review the events surrounding the ends of the four hyperinflations.⁹

However, it will be useful first to expand a little more generally on the distinction between the effects of isolated *actions* taken within the context

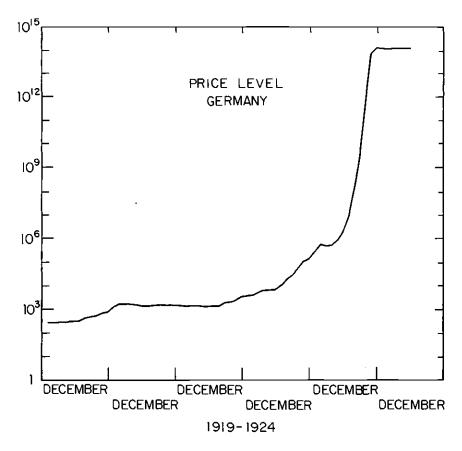

Fig. 2.4 Wholesale prices in Germany.

of a given general strategy, on the one hand, and the effects of choosing among alternative general strategies or rules for repeatedly taking actions, on the other. The latter choice I refer to as a choice of regime. The values of government expenditures and tax rates for one particular quarter are examples of actions, while the rules, implicit or explicit, for repeatedly selecting government expenditures and tax rates as functions of the state of the economy are examples of regimes. Recent work in dynamic macroeconomics has discovered the following general principle: whenever there is a change in the government strategy or regime, private economic agents can be expected to change their strategies or rules for choosing consumption rates, investment rates, portfolios, and so on.¹⁰ The reason is that private agents' behavior is selfish, or at least purposeful, so that when the government switches its strategy, private agents usually find it in their best interests to change theirs. One by-product of this principle is that most of the empirical relations captured in standard econometric models cannot be expected to remain constant across contemplated changes in government policy regimes. For this reason, predictions made under the assumption that such relations will remain constant across regime changes ought not to be believed. The estimate that a 1% reduction in inflation would cost \$220 billion GNP annually is one example of such a faulty prediction. When an important change in regime occurs, dynamic macroeconomics would predict that the entire pattern of correlations among variables will change in quantitatively important ways.

While the distinction between isolated actions and strategy regimes is clear in principle, it is an admittedly delicate task to interpret whether particular historical episodes reflect isolated actions within the same old rules of the game or whether they reflect a new set of rules or government strategies." All that we have to go on are the recorded actions actually taken, together with the pronouncements of public officials, laws, legislative votes, and sometimes constitutional provisions. Out of this material we are to fashion a view about the government strategy being used. Common sense suggests and technical econometric considerations confirm the difficulties in making such interpretations in general. Having said this, I believe that the examples discussed below are about as close to being laboratories for studying regime changes as history has provided.

2.3 Austria

At the end of World War I, the Austro-Hungarian empire dissolved into a number of successor states, of which Austria was one. From having been the center of an empire of 625,000 square kilometers and 50 million inhabitants, Austria was reduced to a mere 80,000 square kilometers and 6.5 million inhabitants. Having suffered food scarcities during the war that were produced by an effective Allied blockade, Austria found itself confronted with new national borders and trade barriers that cut it off from the food sources formerly within its empire. Further, the government of Austria reabsorbed a large number of Austrian imperial bureaucrats who were no longer welcome in the other successor states. Austrians also faced a large-scale unemployment problem stemming from the need to reconvert the economy to peaceful activities and to adjust to the new national borders. If this were not enough, as a loser of the war Austria owed the Reparation Commission sums that for a long time were uncertain in amount but were presumed eventually to be substantial. The Reparation Commission, in effect, held a blanket mortgage against the assets and revenues of the Austrian government.

Austria responded to these pressing problems by making large expenditures in the form of food relief and payments to the unemployed. In addition, the state railroads and monopolies ran deficits, as taxes and prices were kept relatively low. The government did not collect enough taxes to cover expenditures and so ran very substantial deficits during the years 1919–22 (see table A1). As table A1 shows, in these years the deficit was typically over 50 percent of the total government expenditures. The government financed these deficits by selling treasury bills to the Austrian section of the Austro-Hungarian bank. The result was a very rapid increase in the volume of "high-powered" money, defined as the notes and demand deposit obligations of the central bank (see table A2). As the figures in table A2 indicate, between March 1919 and August 1922 the total note circulation in Austria¹² of the Austro-Hungarian bank increased by a factor of 288. This expansion of central bank notes stemmed mainly from the bank's policy of discounting treasury bills. However, it also resulted partly from the central bank's practice of making loans and discounts to private agents at nominal interest rates of between 6 and 9% per annum, rates which by any standard were far too low in view of the inflation rate, which averaged 10,000% per annum from January 1921 to August 1922 (table A3).¹³

In response to these government actions and what seemed like prospects for their indefinite continuation, the Austrian crown depreciated internationally and domestic prices rose rapidly (see tables A3 and A4). While between January 1921 and August 1922 the note circulation of the central bank increased by a factor of 39, the retail price index increased by a factor of 110 (see tables A3 and A4) so that the real value of the note circulation diminished during the currency depreciation.¹⁴ The "flight from the crown" occurred as people chose to hold less of their wealth in the form of the rapidly depreciating crown, attempting instead to hold foreign currencies or real assets.¹⁵ From the viewpoint of financing its deficit, the government of Austria had an interest in resisting the flight from the crown, because this had the effect of diminishing the resources that the government could command by printing money. Therefore the government established a system of exchange controls administered by an agency called the Devisenzentrale. The essential function of this

agency was to increase the amount of Austrian crowns held by Austrians, which it accomplished by adopting measures making it difficult or illegal for Austrians to hold foreign currencies and other substitutes for Austrian crowns.¹⁶ Despite these regulations, it is certain that Austrian citizens were holding large amounts of foreign currencies during 1921 and 1922.

Table A4 reveals that the Austrian crown abruptly stabilized in August 1922, while table A3 indicates that prices abruptly stabilized a month

Table A4 Exchange Rates, Austrian Crowns per United States Dollar, in New York Market

Source: Young [36, vol. 2, p. 294].

later. This occurred despite the fact that the central bank's note circulation continued to increase rapidly, as table A1 indicates. Furthermore, there occurred no change in currency units or "currency reform," at least not for another year and a half.

The depreciation of the Austrian crown was suddenly stopped by the intervention of the Council of the League of Nations and the resulting binding commitment of the government of Austria to reorder Austrian fiscal and monetary strategies dramatically. After Austria's increasingly desperate pleas to the Allied governments for international aid had repeatedly been rejected or only partially fulfilled, in late August 1922 the Council of the League of Nations undertook to enter into serious negotiations to reconstruct the financial system of Austria. These negotiations led to the signing of three protocols on 2 October 1922 which successfully guided the financial reconstruction of Austria. It is remarkable that even before the precise details of the protocols were publicly announced, the fact of the serious deliberations of the Council brought relief to the situation. This can be seen in tables A3 and A4, and was described by Pasvolsky as follows:

The moment the Council of the League decided to take up in earnest the question of Austrian reconstruction, there was immediately a widespread conviction that the solution of the problem was at hand. This conviction communicated itself first of all to that delicately adjusted mechanism, the international exchange market. Nearly two weeks before Chancellor Seipel officially laid the Austrian question before the Council of the League, on August 25, the foreign exchange rate ceased to soar and began to decline, the internal price level following suit three weeks later. The printing presses in Austria were still grinding out new currency; the various ministries were still dispersing this new currency through the country by means of continuing budgetary deficits. Yet the rate of exchange was slowly declining. The crisis was checked.¹⁷

The first protocol was a declaration signed by Great Britain, France, Italy, Czechoslovakia, and Austria that reaffirmed the political independence and sovereignty of Austria.¹⁸ The second protocol provided conditions for an international loan of 650 million gold crowns to Austria. The third protocol was signed by Austria alone and laid out a plan for reconstruction of its fiscal and monetary affairs. The Austrian government promised to establish a new independent central bank, to cease running large deficits, and to bind itself not to finance deficits with advances of notes from the central bank. Further, the government of Austria agreed to accept in Austria a commissioner general, appointed by the Council of the League, who was to be responsible for monitoring the fulfillment of Austria's commitments. The government of Austria also agreed to furnish security to back the reconstruction loan. At the same time, it was understood that the Reparation Commission would give up or modify its claim on the resources of the government of Austria.

The government of Austria and the League both moved swiftly to execute the plan outlined in the protocols. In legislation of 14 November 1922, the Austrian National Bank was formed to replace the old Austrian section of the Austro-Hungarian bank; it was to take over the assets and functions of the Devisenzentrale. The new bank began operations on 1 January 1923 and was specifically forbidden from lending to the government except on the security of an equal amount of gold and foreign assets. The bank was also required to cover its note issues with certain minimal proportions of gold, foreign earning assets, and commercial bills. Further, once the government's debt to the bank had been reduced to 30 million gold crowns, the bank was obligated to resume convertibility into gold.

The government moved to balance its budget by taking concrete steps in several directions. Expenditures were reduced by discharging thousands of government employees. Under the reconstruction scheme, the government promised gradually to discharge a total of 100,000 state employees. Deficits in government enterprises were reduced by raising prices of government-sold goods and services. New taxes and more efficient means of collecting tax and custom revenues were instituted. The results of these measures can be seen by comparing the figures in table A5 with those in table A1. Within two years the government was able to balance the budget.

The stabilization of the Austrian crown was not achieved via a currency reform. At the end of 1924 a new unit of currency was introduced, the schilling, equal to 10,000 paper crowns. The introduction of this new unit

	C	losed Accour	its
Item	1923	1924	1925

Note: 1 schilling = 10,000 paper crowns.

of currency occurred long after the exchange rate had been stabilized and was surely an incidental measure.¹⁹

Table A2 reveals that from August 1922, when the exchange rate suddenly stabilized, to December 1924, the circulating notes of the Austrian central bank increased by a factor of over 6. The phenomenon of the achievement of price stability in the face of a sixfold increase in the stock of "high-powered" money was widely regarded by contemporaries as violating the quantity theory of money, and so it seems to do. However, these observations are not at all paradoxical when interpreted in the light of a view which distinguishes sharply between unbacked, or "outside," money, on the one hand, and backed, or "inside," money, on the other hand. In particular, the balance sheet of the central bank and the nature of its open market operations changed dramatically after the carrying out of the League's protocols, with the consequence that the proper intrepretation of the figures on the total note obligations of the central bank changes substantially. Before the protocols, the liabilities of the central bank were backed mainly by government treasury bills; that is, they were not backed at all, since treasury bills signified no commitment to raise revenues through future tax collections. After the execution of the protocols, the liabilities of the central bank became backed by gold, foreign assets, and commercial paper, and ultimately by the power of the government to collect taxes. At the margin, central bank liabilities were backed 100% by gold, foreign assets, and commercial paper as notes and the deposits were created through open market operations in those assets (see table A6). The value of the crown was backed by the commitment of the government to run a fiscal policy compatible with maintaining the convertibility of its liabilities into dollars. Given such a fiscal regime, to a first approximation, the intermediating activities of the central bank did not affect the value of the crown so long as the assets purchased by the bank were sufficiently valuable. Thus the sixfold increase in the liabilities of the central bank after the protocols ought not to be regarded as inflationary. The willingness of Austrians to convert

hoards of foreign exchange into crowns which is reflected in table A6 is not surprising since the stabilization of the crown made it a much more desirable asset to hold relative to foreign exchange.²⁰

The available figures on unemployment indicate that the stabilization of the crown was attended by a substantial increase in the unemployment rate, though unemployment had begun to climb well before stabilization was achieved (see table A7). The number of recipients of state unemploy-

ment benefits gradually climbed from a low of 8,700 in December 1921 to 83,000 in December 1922. It climbed to 167,000 by March 1923, and then receded to 76,000 in November 1923.²¹ How much of this unemployment was due to the achievement of currency stabilization and how much was due to the real dislocations affecting the Austrian economy cannot be determined. However, it is true that currency stabilization was achieved in Austria very suddenly, and with a cost in increased unemployment and foregone output that was minor compared with the \$220 billion GNP that some current analysts estimate would be lost in the United States per one percentage point inflation reduction.

2.4 Hungary

Like its old partner in the Hapsburg monarchy, Hungary emerged from World War I as a country much reduced in land, population, and power. It retained only 25% of its territory (down from 325,000 square kilometers to 92,000) and only 37% of its population (down from 21 million to about 8 million). Its financial and economic life was disrupted by the newly drawn national borders separating it from peoples and economic institutions formerly within the domain of the Hapsburg monarchy.

At the end of the war, Hungary experienced political turmoil as the Hapsburg King Charles was replaced by the government of Prince Karolyi. In March 1919, the Karolyi government was overthrown by the Bolsheviks under Bela Kun. The regime of Bela Kun lasted only four months, as Romania invaded Hungary, occupied it for a few weeks, and then withdrew. A new repressive right wing regime under Admiral Horthy then took power. The "white terror" against leftists carried out by supporters of Horthy took even more lives than the "red terror" that had occurred under Bela Kun.

At the end of the war, the currency of Hungary consisted of the notes of the Austro-Hungarian bank. By the provisions of the peace treaties of Trianon and St. Germain, the successor states to the Austro-Hungarian empire were required to stamp the notes of the Austro-Hungarian bank that were held by their residents, in effect, thereby recognizing those notes as debts of the respective new states. Before Hungary executed this provision of the Treaty of Trianon, the currency situation grew more complicated, for the Bolshevik regime had access to the plates for printing one- and two-crown Austro-Hungarian bank notes and it used them to print more notes. The Bolshevik government also issued new so-called white notes. Each of these Bolshevik-issued currencies was honored by the subsequent government.

The Austro-Hungarian bank was liquidated at the end of 1919, and it was replaced by an Austrian section and a Hungarian section. The functions of the Hungarian section of the old bank were assumed in August 1921 by a State Note Institute, which was under the control of the minister of finance. In August 1921, the Note Institute issued its own notes, the Hungarian krone, in exchange for Hungarian stamped notes of the Austro-Hungarian bank and several other classes of notes, including those that had been issued by the Bolshevik regime.

As a loser of the war, Hungary owed reparations according to the Treaty of Trianon. The Reparation Commission had a lien on the resources of the government of Hungary. However, neither the total amount owed nor a schedule of payments was fixed for many years after the war. This circumstance alone created serious obstacles in terms of achieving a stable value for Hungary's currency and other debts, since the unclear reparations obligations made uncertain the nature of the resources which backed those debts.

From 1919 until 1924 the government of Hungary ran substantial budget deficits. The government's budget estimates in table H1 are reported by Pasvolsky substantially to understate the size of the deficits.²² These deficits were financed by borrowing from the State Note Institute, and were a major cause of a rapid increase in the note and deposit liabilities of the institute. An additional cause of the increase in liabilities of the institute was the increasing volume of loans and discounts that it made to private agents (see table H2). These loans were made at a very

Table H2 (continued)

low interest rate, in view of the rapid rate of price appreciation, and to a large extent amounted to simple gifts from the Note Institute to those lucky enough to receive loans on such generous terms. These private loans account for a much larger increase in high-powered money in the Hungarian than in the other three hyperinflations we shall study.

As table H3 shows, the Hungarian krone depreciated rapidly on foreign exchange markets, and domestic prices rose rapidly. Between January 1922 and April 1924, the price index increased by a factor of 263. In the same period, the total notes and deposit liabilities of the Note Institute increased by a factor of 85, so that the real value of its liabilities decreased substantially. As in the case of Austria, this decrease was symptomatic of a "flight from the krone," as residents of Hungary attempted to economize on their holdings of krones and instead to hold assets denominated in more stable currencies. As in the case of Austria, the government of Hungary resisted this trend by establishing in August 1922 a Hungarian Devisenzentrale within the State Note Institute.

Table H3 indicates that in March 1924, the rise in prices and the depreciation of the krone internationally both abruptly halted. The stabilization occurred in the face of continued expansion in the liabilities of the central bank, which increased by a factor of 3.15 between March 1924 and January 1925 (see table H2). This pattern parallels what occurred in Austria and has a similar explanation.

As in Austria, the financial reconstruction of Hungary was accomplished with the intervention of the League of Nations. Together with the Reparation Commission and the government of Hungary, the League devised a plan which reduced and clarified the reparations commitment of Hungary, arranged for an international loan that would help finance government expenditures, and committed Hungary to establish a balanced budget and a central bank legally bound to refuse any government demand for unbacked credit. On 21 February 1924, the Reparation Commission agreed to give up its lien on Hungary's resources so that these could be used to secure a reconstruction loan. A variety of Western nations also agreed to give up their liens on Hungary so that the new loan could successfully be floated.

The League's reconstruction plan was embodied in two protocols. The first was signed by Great Britain, France, Italy, Czechoslovakia, Rumania, and Hungary, and guaranteed the "political independence, territorial integrity, and sovereignty of Hungary." The second protocol outlined the terms of the reconstruction plan, and committed Hungary to balance its budget and form a central bank truly independent of the Finance Ministry. The government was also obligated to accept in Hungary a commissioner general, responsible to the League, to monitor and supervise the government's fulfillment of its commitment to fiscal and monetary reform.

¹From July 1921 through November 1923, the index numbers represent retail prices and are based on 60 commodities with July 1914 = 100. From December 1923 through March 1925, the figures are based on wholesale prices computed by the Hungarian Central Statistical Office. They refer to the prices of 52 commodities on the last day of the month with 1913 = 100.

A reconstruction loan of 250 million gold krones was successfully placed abroad in July 1924. The loan was secured by receipts from customs duties and sugar taxes, and revenues from the salt and tobacco monopolies. The purpose of the loan was to give the government a concrete means of converting future promises to tax into current resources while avoiding the need to place its debt domestically.

By a law of 26 April 1924, the Hungarian National Bank was established, and it began operations on 24 June. The bank assumed the assets and liabilities of the State Note Institute and took over the functions of the foreign exchange control office, the Devisenzentrale. The bank was prohibited from making any additional loans or advances to the government, except upon full security of gold or foreign bills. The bank was also required to hold gold reserves of certain specified percentages behind its liabilities.

The government of Hungary also tried to establish a balanced budget. Both by cutting expenditures and raising tax collections, the government was successful in moving quickly to a balanced budget (see table H4). Indeed, the proceeds of the reconstruction loan were used perceptibly more slowly than had been anticipated in the reconstruction plan.

As table H2 confirms, the stabilization of the krone was accompanied by a substantial *increase* in the total liabilities of the central bank. But as with Austria, the drastic shift in the fiscal policy regime that occasioned the stabilization also changed the appropriate interpretation of these figures. As table H2 indicates and as the regulations governing the bank required, after the League's intervention the note and deposit liabilities

of the central bank became backed, 100% at the margin, by holdings of gold, foreign exchange, and commercial paper. In effect, the central bank's liabilities represented "fiat money" before the League's plan was in effect; after that plan was in effect, they represented more or less backed claims on British sterling,23 the foreign currency to which Hungary pegged its exchange as a condition for British participation in the reconstruction loan.

Figures on unemployment in Hungary are reported in table H5, and unfortunately begin only immediately after the price stabilization had already occurred. All that can be inferred from these figures is that immediately after the stabilization, unemployment was not any higher than it was one or two years later. This is consistent either with the hypothesis that the stabilization process had little adverse effect on

unemployment or with the hypothesis that the adverse effect was so long-lasting that no recovery occurred within the time span of the figures recorded. The former hypothesis seems more plausible to me.

2.5 Poland

The new nation of Poland came into existence at the end of World War I, and was formed from territories formerly belonging to Germany, Austro-Hungary, and Russia. At the time of its formation, Poland possessed a varied currency consisting of Russian rubles, crowns of the Austro-Hungarian bank, German marks, and Polish marks issued by the Polish State Loan Bank, which had been established by Germany to control the currency in the part of Poland occupied by Germany during the war. For Poland, the armistice of 1918 did not bring peace, a costly war with Soviet Russia being waged until the fall of 1920. Poland was devastated by the fighting and by Germany's practice of stripping it of its machinery and materials during World War I.²⁴

The new government of Poland ran very large deficits up to 1924 (see table P1). These deficits were financed by government borrowing from the Polish State Loan Bank, which the new government had taken over from the Germans. From January 1922 to December 1923, the outstanding notes of the Polish State Loan Bureau increased by a factor of 523 (table P2). Over the same period, the price index increased by a factor of

2,402 while the dollar exchange rate decreased by a factor of 1,397 (see tables P3 and P4). As in the other inflations we have studied, the real value of the note circulation decreased as people engaged in a "flight from the mark." Extensive government exchange controls were imposed to resist this trend.

Tables P2 and P3 indicate that the rapid inflation and exchange depreciation both suddenly stopped in January 1924. Unlike the cases of Austria and Hungary, in Poland the initial stabilization was achieved without foreign loans or intervention, although later in 1927, after currency depreciation threatened to renew, a substantial foreign loan was arranged.²⁵ But in terms of the substantial fiscal and monetary regime changes that accompanied the end of the inflation, there is much similarity to the Austrian and Hungarian experiences. The two interrelated

changes were a dramatic move toward a balanced government budget and the establishment of an independent central bank that was prohibited from making additional unsecured loans to the government. In January 1924, the minister of finance was granted broad powers to effect monetary and fiscal reform. The minister immediately initiated the establishment of the Bank of Poland, which was to assume the functions of the Polish State Loan Bank. The eventual goal was to restore convertibility with gold. The bank was required to hold a 30% reserve behind its notes, to consist of gold and foreign paper assets denominated in stable currencies. Beyond this reserve, the bank's notes had to be secured by private bills of exchange and silver. A maximum credit to the government of 50 million zlotys was permitted. The government also moved swiftly to balance the budget (see table P1).

In January 1924, a new currency unit became effective, the gold zloty, worth 1.8 million paper marks. The zloty was equal in gold content to 19.29 cents.

Table P2 reveals that, from January 1924 to December 1924, the note circulation of the central bank increased by a factor of 3.2, in the face of relative stability of the price level and the exchange rate (see tables P3 and P4). This phenomenon matches what occurred in Austria and Hun-

gary and has a similar explanation. As table P2 reveals, the increased note circulation during this period was effectively backed 100% by gold, foreign exchange, and private paper.

The available figures on unemployment are summarized in table P5. The stabilization of the price level in January 1924 is accompanied by an abrupt rise in the number of unemployed. Another rise occurs in July of 1924. While the figures indicate substantial unemployment in late 1924, unemployment is not an order of magnitude worse than before the stabilization, and certainly not anywhere nearly as bad as would be predicted by application of the same method of analysis that was used to fabricate the prediction for the contemporary United States that each percentage point reduction in inflation would require a reduction of \$220 billion in real GNP.

The Polish zloty depreciated internationally from late 1925 onward but stabilized in autumn of 1926 at around 72% of its level of January 1924. At the same time, the domestic price level stabilized at about 50% above its level of January 1924. The threatened renewal of inflation has been attributed to the government's premature relaxation of exchange controls and the tendency of the central bank to make private loans at insufficient interest rates.²⁶

2.6 Germany

After World War I, Germany owed staggering reparations to the Allied countries. This fact dominated Germany's public finance from 1919 until 1923 and was a most important force for hyperinflation.

Allied countries. This fact dominated Germany's public finance from 1919 until 1923 and was a most important force for hyperinflation. At the conclusion of the war, Germany experienced a political revolution and established a republican government. The early postwar governments were dominated by moderate Socialists, who for a variety of reasons reached accommodations with centers of military and industrial power of the prewar regime.²⁷ These accommodations in effect undermined the willingness and capability of the government to meet its admittedly staggering revenue needs through explicit taxation.

Of the four episodes that we have studied, Germany's hyperinflation was the most spectacular, as the figures on wholesale prices and exchange rates in tables G1 and G2 reveal. The inflation became most severe after the military occupation of the Ruhr by the French in January 1923. The German government was determined to fight the French occupation by a policy of passive resistance, making direct payments to striking workers which were financed by discounting treasury bills with the Reichsbank.

policy of passive resistance, making direct payments to striking workers which were financed by discounting treasury bills with the Reichsbank. Table G3 estimates the budget of Germany for 1920 to 1923.²⁸ The table reveals that, except for 1923, the budget would not have been badly out of balance except for the massive reparations payments made. The disruption caused to Germany's finances by the reparations situation is

surely understated by the reparations figures given in table G3. For one thing, considerably larger sums were initially expected of Germany than it ever was eventually able to pay. For another thing, the extent of Germany's total obligation and the required schedule of payments was for a long time uncertain and under negotiation. From the viewpoint that the value of a state's currency and other debt depends intimately on the fiscal policy it intends to run, the uncertainty about the reparations owed by the German government necessarily cast a long shadow over its prospects for a stable currency.

As table G4 reveals, the note circulation of the Reichsbank increased dramatically from 1921 to 1923, especially in the several months before November 1923. As pointed out by Young [36], at the end of October 1923, over 99% of outstanding Reichsbank notes had been placed in circulation within the previous 30 days.²⁹ Table G4 reveals the extent to which the Reichsbank note circulation was backed by discounted treasury bills. During 1923, the Reichsbank also began discounting large volumes of commercial bills. Since these loans were made at nominal rates of interest far below the rate of inflation, they amounted virtually to government transfer payments to the recipients of the loans. Especially during the great inflation of 1923, a force came into play

Especially during the great inflation of 1923, a force came into play which was also present in the other hyperinflations we have studied.

Given the method of assessing taxes in nominal terms, lags between the time when taxes were levied and the time when they were collected led to reduced revenues as the government evidently repeatedly underestimated the prospective rate of inflation and as the rapid inflation gave people a large incentive to delay paying their taxes. This effect probably partially accounts for the reduced tax revenues collected during the first nine months of 1923. The French occupation of the Ruhr also helps explain it.

In response to the inflationary public finance and despite the efforts of the government to impose exchange controls, there occurred a "flight from the German mark" in which the real value of Reichsmark notes decreased dramatically. The figures in table G1 indicate that between January 1922 and July 1923, wholesale prices increased by a factor of 2,038 while Reichsbank notes increased by a factor of 378. Between January 1922 and August 1923, wholesale prices increased by a factor of 25,723 while Reichsbank notes circulating increased by a factor of 5,748. The fact that prices increased proportionately many times more than did the Reichsbank note circulation is symptomatic of the efforts of Germans to economize on their holdings of rapidly depreciating German marks. Toward the end of the hyperinflation. Germans made every effort to avoid holding marks and held large quantities of foreign exchange for purposes of conducting transaction. By October 1923, it has been roughly estimated, the real value of foreign currencies circulating in Germany was at least equal to and perhaps several times the real value of Reichsbank notes circulating.30

The figures in tables G1 and G2 show that prices suddenly stopped rising and the mark stopped depreciating in late November 1923. The event of stabilization was attended by a "monetary reform," in which on 15 October 1923 a new currency unit called the Rentenmark was declared equivalent to 1 trillion (10^{12}) paper marks. While great psychological

Footnotes to Table G4

Source: Young [36, vol. 1, pp. 528-29].

Note: End of month figures, in thousands of current marks; from January 1924 in thousands of rentenmarks or reichsmarks. 1 rentenmark is equivalent to 1 reichsmark or 1 trillion (10¹²) former paper marks. The reichsmark is the equivalent of the gold mark worth 23.82 cents.

¹The large increase of advances at the close of November 1922 occurred because the Reichsbank had to take over temporarily the financing of food supplies from the loan bureaus (Darlehuskassen), as the latter were unable to extend the needed accommodation, their outstanding notes having reached the maximum amount permitted by law.

²In billions.

 $^{^{3}}A$ decree of 15 November 1923 discontinued the discounting of treasury bills by the Reichsbank.

⁴See note above.

⁵Date of first statement of reorganized Reichsbank.

significance has sometimes been assigned to this unit change, it is difficult to attribute any substantial effects to what was in itself only a cosmetic measure.³¹ The substantive aspect of the decree of 15 October was the establishing of a Rentenbank to take over the note issue functions of the Reichbank. The decree put binding limits upon both the total volume of Rentenmarks that could be issued, 3.2 billion marks, and the maximum amount that could be issued to the government, 1.2 billion marks. This limitation on the amount of credit that could be extended to the government was announced at a time when the government was financing virtually 100% of its expenditures by means of note issue.³² In December 1923, the management of the Rentenbank was tested by the government and effectively made clear its intent to meet its obligation to limit government borrowing to within the amount decreed.

Simultaneously and abruptly three things happened: additional government borrowing from the central bank stopped, the government budget swung into balance, and inflation stopped. Table G5 shows the dramatic progress toward a balanced budget that was made in the months after the Rentenbank decree.

The government moved to balance the budget by taking a series of deliberate, permanent actions to raise taxes and eliminate expenditures.

 Ordinary Revenues and Expenditures of the German Federal Government (from Wirtschift and Statistik, issued by the Statistisches Reichsamt, in millions of gold marks)

Source: Young [36, vol. 1, p. 422].

Young reports that "by the personnel decree of October 27, 1923, the number of government employees was cut by 25 percent; all temporary employees were to be discharged; all above the age of 65 years were to be retired. An additional 10 percent of the civil servants were to be discharged by January 1924. The railways, overstaffed as a result of post-war demobilization, discharged 120,000 men during 1923 and 60,000 more during 1924. The postal administration reduced its staff by 65,000 men; the Reichsbank itself which had increased the number of its employees from 13,316 at the close of 1922 to 22,909 at the close of 1923, began the discharge of its superfluous force in December, as soon as the effects of stabilization became manifest."³³

Substantially aiding the fiscal situation, Germany also obtained relief from her reparation obligations. Reparations payments were temporarily suspended, and the Dawes plan assigned Germany a much more manageable schedule of payments.

Table G4 documents a pattern that we have seen in the three other hyperinflations: the substantial growth of central bank note and demand deposit liabilities in the months *after* the currency was stabilized. As in the other cases that we have studied, the best explanation for this is that at the margin the postinflation increase in notes was no longer backed by government debt. Instead, in the German case, it was largely backed by discounted commercial bills. The nature of the system of promises and claims behind the central bank's liabilities changed when after the Rentenbank decree the central bank no longer offered additional credit to the government. So once again the interpretation of the time series on central bank notes and deposits must undergo a very substantial change.

By all available measures, the stabilization of the German mark was accompanied by increases in output and employment and decreases in unemployment.³⁴ While 1924 was not a good year for German business, it was much better than 1923. Table G6 is representative of the figures assembled by Graham, and shows that 1924 suffers in comparison with 1922 but that 1925 was a good year. In these figures one cannot find much convincing evidence of a favorable trade-off between inflation and out-

Table G6	Index of Physical Volume of Production per Capita in Germany						
	Year	Index of Production	Year	Index of Production			
	192 0	61	1924	77			
	1921	77	1925	90			
	1922	86	1926	86			
	1923	54	1927	111			

Source: Graham [7, p. 287].

put, since the year of spectacular inflation, 1923 was a very bad year for employment and physical production. Certainly a large part of the poor performance of 1923 was due to the French occupation of the Ruhr and the policy of passive resistance.

Despite the evident absence of a "Phillips curve" trade-off between inflation and real output in the figures in tables G1 and G6, there is ample evidence that the German inflation was far from "neutral" and that there were important "real effects." Graham [7] gives evidence that the inflation and the associated reduction in real rates of return to "highpowered" money and other government debt were accompanied by real overinvestment in many kinds of capital goods.³⁵ There is little doubt that the "irrational" structure of capital characterizing Germany after stabilization led to subsequent problems of adjustment in labor and other markets.

2.7 Czechoslovakia

After World War I, the new nation of Czechoslovakia was formed out of territories formerly belonging to Austria and Hungary. Under the leadership of a distinguished minister of finance, Dr. Alois Rasin, immediately after the war Czechoslovakia adopted the conservative fiscal and monetary policies its neighbors adopted only after their currencies had depreciated radically. As a result, Czechoslovakia avoided the hyperinflation experienced by its neighbors.

Under Rasin's leadership, Czechoslovakia early on showed that it was serious about attaining a stable currency. Even before the peace treaties required it, Czechoslovakia stamped the Austro-Hungarian notes then circulating within its border with the Czechoslovakian stamp, thereby recognizing them as its own debt. There was considerable drama associated with this event, as the National Assembly passed the plans for stamping in secret sessions on 25 February 1919. From 26 February to 9 March, the frontiers of the country were unexpectedly closed and foreign mail service was closed. Only Austro-Hungarian notes circulating within the country could be presented for stamping. As part of the stamping process, the government retained part of the notes in the form of a forced loan.³⁶ About 8 billion crowns were stamped.

A banking office in the Ministry of Finance took over the affairs of the old Austro-Hungarian bank. Czechoslovakia moved quickly to limit by statute the total government note circulation and to prevent inflationary government finance. A law of 10 April 1919 strictly limited the fiduciary or unbacked note circulation of the banking office to about 7 billion crowns. This law was obeyed, and forced the government to finance its expenditures by levying taxes or else issuing debt, which, because of the statutory restriction on government note issues, were interpreted as promises to tax in the future.

From 1920 on, Czechoslovakia ran only modest deficits on current account (see table C1). Among other taxes, Czechoslovakia imposed a progressive capital levy on property, which raised a cumulative amount of about 11 billion crowns by 1925. It also imposed an increment tax on the increased wealth individuals had obtained during the war.

Table C2 shows the note and deposit liabilities of the banking office. The government's abstention from inflationary finance shows up in these figures.

restore the Czechoslovakia crown to the prewar gold par value of the old Austro-Hungarian crown. Following Rasin's assassination, this plan was abandoned and the crown was stabilized at about 2.96 cents.

2.8 Conclusion

The essential measures that ended hyperinflation in each of Germany, Austria, Hungary, and Poland were, first, the creation of an independent central bank that was legally committed to refuse the government's demand for additional unsecured credit and, second, a simultaneous alteration in the fiscal policy regime.³⁷ These measures were interrelated and coordinated. They had the effect of binding the government to place its debt with private parties and foreign governments which would value that debt according to whether it was backed by sufficiently large prospective taxes relative to public expenditures. In each case that we have studied, once it became widely understood that the government would not rely on the central bank for its finances, the inflation terminated and the exchanges stabilized. We have further seen that it was not simply the increasing quantity of central bank notes that caused the hyperinflation, since in each case the note circulation continued to grow rapidly after the exchange rate and price level had been stabilized. Rather, it was the growth of fiat currency which was unbacked, or backed only by government bills, which there never was a prospect to retire through taxation.

The changes that ended the hyperinflations were not isolated restrictive actions within a given set of rules of the game or general policy. Earlier attempts to stabilize the exchanges in Hungary under Hegedus,³⁸ and also in Germany, failed precisely because they did not change the rules of the game under which fiscal policy had to be conducted.³⁹

In discussing this subject with various people, I have encountered the view that the events described here are so extreme and bizarre that they do not bear on the subject of inflation in the contemporary United States. On the contrary, it is precisely because the events were so extreme that they are relevant. The four incidents we have studied are akin to laboratory experiments in which the elemental forces that cause and can be used to stop inflation are easiest to spot. I believe that these incidents are full of lessons about our own, less drastic predicament with inflation, if only we interpret them correctly.

Notes

1. "Most economists believe that the underlying inflation rate—roughly defined as wage costs less productivity gains—now stands at 9 to 10 percent, and that only a long period of restraint can reduce that rate significantly" (*Newsweek*, 19 May 1980, p. 59).

2. Paul Samuelson has aptly summarized the rational expectations view: "I should report that there is a new school, the so-called 'rational expectationists.' They are optimistic that inflation can be wiped out with little pain if only the government makes *credible* its determination to do so. But neither history nor reason tempt one to bet their way" (*Newsweek*, 28 April 1980). The second sentence of this quote is probably as shrewd a summary of the rational expectations view as can be made in a single sentence. However, it is difficult to agree with the third sentence: as for "reason," no one denies that logically coherent and well-reasoned models underlie the claims of the "rational expectationists"; as for history, the evidence summarized in this paper is surely relevant.

3. There is actually no such thing as a "rational expectations school" in the sense of a collection of economists with an agreed upon model of the economy and view about optimal monetary and fiscal policy. In fact, among economists who use the assumption of rational expectations there is wide disagreement about these matters. What characterizes adherents of the notion of rational expectations is their intention to build models by assuming that private agents understand the dynamic environment in which they operate approximately as well as do government policymakers. Adherence to this notion leaves ample room for substantial diversity about the many other details of a model. For some examples of rational expectations models with diverse implications, see Lucas [21]. Barro [2]. Wallace [35]. Townsend [34], and Sargent and Wallace [31]. Despite their diversity, it is true that all of these models impel us to think about optimal government policy in substantially different ways than were standard in macroeconomics before the advent of the doctrine of rational expectations in the early 1970s.

4. Bresciani-Turroni wrote: "Whoever studies the recent economic history of Europe is struck by a most surprising fact: the rapid monetary restoration of some countries where for several years paper money had continually depreciated. In some cases the stabilization of the exchange was not obtained by a continuous effort, prolonged over a period of years, whose effects would show themselves slowly in the progressive economic and financial restoration of the country, as occurred before the War in several well-known cases of monetary reform. Instead, the passing from a period of tempestuous depreciation of the currency to an almost complete stability of the exchange was very sudden" [3, p. 334]. Compare these remarks with the opinion of Samuelson cited in note 2 above.

5. The notes were "backed" mainly by treasury bills which, in those times, could not be expected to be paid off by levying taxes, but only by printing more notes or treasury bills. 6. League of Nations [13, p. 101].

7. Keynes wrote: "It is not lack of gold but the absence of other internal adjustments which prevents the leading European countries from returning to a pre-war gold standard. Most of them have plenty of gold for the purpose as soon as the other conditions favorable to the restoration of a gold standard have returned" (Keynes [11, p. 132]). Writing about Germany in 1923, Keynes said: "The government cannot introduce a sound money, because, in the absence of other revenue, the printing of an unsound money is the only way by which it can live" (Keynes [10, p. 67]).

8. This view can be expressed more precisely by referring to the technical literature of optimum economic growth. I am recommending that a good first model of the gold standard or other commodity money is a real equilibrium growth model in which a government issues debt, makes expenditures, and collects taxes. Examples of these models were studied by Arrow and Kurz [1]. In such models, government debt is valued according to the same economic considerations that give private debt value, namely, the prospective net revenue stream of the institution issuing the debt. A real equilibrium growth model of this kind can also be used to provide a formal rationalization of my claim below that open market operations in private securities, foreign exchange, and gold should have no effect on the price level, i.e. the value of government demand debt.

9. It is relatively straightforward to produce a variety of workable theoretical models of a commodity money or gold standard, along the lines of note 8. It is considerably more difficult to produce a model of a fiat money, which is costless to produce, inconvertible, and of no utility except in exchange. Kareken and Wallace [9], Wallace [35], and Townsend [34] describe some of the ramifications of this observation. The workable models of fiat money that we do have—for example, those of Townsend [34] and Wallace [35]—immediately raise the question of whether voluntarily held fiat money can continue to be valued at all in the face of substantial budget deficits of the order of magnitude studied in this paper. Such models lead one to assign an important role to government restrictions, particularly on foreign exchange transactions, in maintaining a valued, if involuntarily held, fiat money. Keynes [10] and Nichols [24] also emphasized the role of such restrictions.

10. The sweeping implications of this principle for standard ways of formulating and using econometric models were first described by Lucas [19]. The principle itself has emerged in a variety of contexts involving economic dynamics. For some examples, see Lucas [20] and Sargent and Wallace [30].

11. Sargent and Wallace [32] describe a sense in which it might be difficult to imagine that a regime change can occur. As they discovered, thinking about regime changes in the context of rational expectations models soon leads one to issues of free will.

12. The Treaty of St. Germain, signed in September of 1919, required the successor states of the Austro-Hungarian empire to stamp their share of the notes of the Austro-Hungarian bank. The stamp converted those notes to the currency, i.e. debt, of the new states. The Austrian section of the old Austro-Hungarian bank functioned as the central bank of Austria for several years after the war.

13. Needless to say, the central bank encountered a strong demand for loans at this rate and had to ration credit.

14. At the time, some commentators argued that since the real value of currency had decreased and so in a sense currency was scarce, the increased note issue of the central bank was not the prime cause of the inflation. Some even argued that money was "tight" and that the central bank was valiantly struggling to meet the shortage of currency by adding printing presses and employees. This argument is now widely regarded as fallacious by macroeconomists. Disturbingly, however, one hears the very same argument in the contemporary United States.

15. "In Vienna, during the period of collapse, mushroom exchange banks sprang up at every street corner, where you could change your krone into Zurich francs within a few minutes of receiving them, and so avoid the risk of loss during the time it would take you to reach your usual bank. It became a reasonable criticism to allege that a prudent man at a cafe ordering a bock of beer should order a second bock at the same time, even at the expense of drinking it tepid, lest the price should rise meanwhile" (Keynes [10, p. 51]).

16. See Young [36, vol. 2, p. 16]. That a government might want to adopt such measures if it were using inflationary finance was pointed out by Nichols [24].

17. Pasvolsky [25, p. 116].

18. The content of this protocol is highly sensible when it is remembered that the value of a state's currency and other debt, at least under the gold standard, is determined by its ability to back that debt with an appropriate fiscal policy. In this respect, its situation is no different from that of a firm. In 1922, there was widespread concern within and without Austria that its sovereignty was at risk. (See the desperate note delivered by the Austrian minister to the Supreme Council of the Allied governments quoted by Pasvolsky [25, p. 115]). The first protocol aimed to clarify the extent to which Austria remained a political and economic entity capable of backing its debts. A similar protocol was signed at the inception of Hungary's financial reconstruction.

19. It should be noted that for two years the new bank vigorously exercised its authority to control transactions in foreign currency. Only after March 1925 were restrictions on trading foreign exchange removed.

20. This explanation is consistent with the argument advanced by Fama [6]. There is an alternative explanation of these observations that neglects the distinction between inside and outside money, and that interprets the observations in terms of a demand function for the total quantity of "money." For instance, Cagan [4] posited the demand schedule for money to take the form

(1)
$$M_t - P_t = \alpha (E_t P_{t+1} - P_t), \quad \alpha < 0,$$

where P_t is the logarithm of the price level, M_t is the logarithm of the money supply, and $E_t P_{t+1}$ is people's expectation of the log of price next period. There is always a problem in defining an empirical counterpart to M_t , but it is often taken to be the note and deposit liabilities of the central bank or "high-powered" money. The money demand schedule or "portfolio balance" schedule incorporates the idea that people want to hold less wealth in the form of real balances the faster the currency is expected to depreciate. Equation (1) can be solved to give an expression for the equilibrium price level of the form

(2)
$$P_{t} = \frac{1}{1-\alpha} \sum_{i=0}^{\infty} \left(\frac{\alpha}{\alpha-1}\right)^{i} E_{t} M_{t+i},$$

where $E_t M_{t+i}$ is what at time t people expect the money supply to be at time t+i.

Consider the following two experiments. First, suppose that the government engages in a policy, which everyone knows in advance, of making the money supply grow at the constant high rate $\mu > 0$ from time 0 to time T - 1, and then at the rate zero from time T onward. In this case, the inflation rate would follow the path depicted in figure 2.N.1.

For the second experiment, suppose that initially everyone expected the money supply to increase at the constant rate μ forever but that at time T it becomes known that henceforth the money supply will increase at the rate 0 forever. In this case, the inflation rate takes a

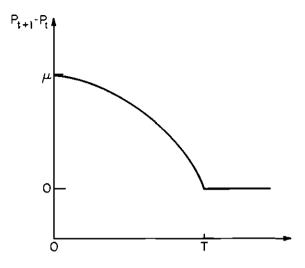

Fig. 2.N.1 Inflation path with an expected decrease in money supply growth from μ to 0 at time T.

sudden drop at time T, as shown by the path in figure 2.N.2. Now since the inflation and the expected inflation rate experience a sudden drop at T in this case, it follows from equation (1) that real balances must increase at T. This will require a sudden once and for all *drop* in the price level at T.

This second example of a previously unexpected decrease in the inflation rate provides the material for an explanation of the growth of the money supplies after currency stabilization. In the face of a previously unexpected, sudden, and permanent drop in the rate of money creation, the only way to avoid a sudden drop in the price level would be to

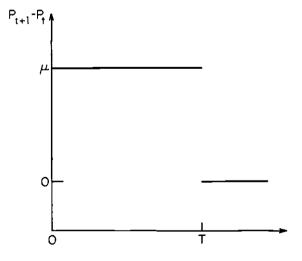

Fig. 2.N.2 Inflation path with a previously unexpected decrease in money supply growth from μ to 0 at time T.

Thomas J. Sargent

accompany the decrease in the rate of money creation with a once and for all increase in the money supply. In order to stabilize the price level in the face of a decreased rate of change of money, the level of the money supply must jump upward once and for all.

What actually occurred in the four countries studied here was not a once and for all jump but a gradual increase in the money supply over many months. This could be reconciled with the observations within the model (1) if people were assumed only gradually to catch on to the fact of stabilization and to decrease the rate of inflation that they expected as the currency stabilization continued to hold. I find this explanation hard to accept, but it is a possibility.

An alternative way to reconcile the preceding explanation with the gradual upward movement of "high-powered" money after the stabilizations is to add adjustment lags to the portfolio balance schedule (1). For example, consider replacing (1) with

(1')
$$(M_t - P_t) = \alpha(E_t P_{t+1} - P_t) + \lambda(M_{t-1} - P_{t-1}) \\ \alpha < 0, \ 0 < \lambda < 1.$$

In this case, an abrupt stabilization of expected inflation induces only a gradual adjustment of real balances upward at the rate of $1 - \lambda$ per period. My own preference at this point is for an explanation that stresses the distinction between backed and unbacked money.

21. See Pasvolsky [25, p. 161].

22. See Pasvolsky [25, p. 298].

23. Within a year and a half, these became a claim on gold as Britain returned to the gold standard.

24. Unlike Austria, Hungary, and Germany, Poland did not owe war reparations.

- 27. See the account in Paxton [26, pp. 146-50].
- 28. Also see Graham [7, pp. 40-41].

29. Keynes wrote: "A government can live for a long time, even the German government or the Russian government, by printing paper money . . . A government can live by this means when it can live by no other" (Keynes [10, p. 47]).

30. See Young [36, vol. 1, p. 402] and Bresciani-Turroni [3, p. 345].

31. After reading an earlier draft of this paper, John Kennan directed me to the following passage in Constance Reid's biography of the mathematician Hilbert: "In 1923 the inflation ended abruptly through the creation of a new unit of currency called the Rentenmark. Although Hilbert remarked sceptically, 'One cannot solve a problem by changing the name of the independent variable,' the stability of conditions was gradually restored" (Reid [27, pp. 162-63]).

- 32. Young [36, vol. 1, p. 421].
- 33. Young [36, vol. 1, p. 422].
- 34. See Graham [7, chapter 12].

35. Theoretical models of money along the lines proposed by Samuelson [29] predict that too much capital will be accumulated when the government fiscal policy is so profligate that money becomes valueless. See Samuelson [29] and Wallace [35].

36. The frontiers were closed to prevent notes from Austria and Hungary from entering the country. The Treaty of St. Germain, signed 10 September 1919, provided that the successor states should stamp the Austro-Hungarian notes, signifying their assumption of the debt.

37. Of inflationary finance, Keynes wrote: "It is common to speak as though, when a government pays its way by inflation, the people of the country avoid taxation. We have seen this is not so. What is raised by printing notes is just as much taken from the public as is beer-duty or an income-tax. What a government spends the public pay for. There is no such thing as an uncovered deficit. But in some countries it seems possible to please and content the public, for a time at least, by giving them, in return for the taxes they pay, finely

94

engraved acknowledgments on water-marked paper. The income tax receipts, which we in England receive from the surveyor, we throw into the wastepaper basket: in Germany they call them bank-notes and put them into their pocketbooks: in France they are termed Rentes and are locked up in the family safe" (Keynes [10, pp. 68–69]).

38. See Pasvolsky [25, pp. 304-7].

39. A deep objection to the interpretation in this paragraph can be constructed along the fines of Sargent and Wallace [30], who argue that for a single economy it is impossible to conceive of a rational expectations model in which there can occur a change in regime. In particular, the substantial changes in ways of formulating monetary and fiscal policy associated with the ends of the four inflations studied here can themselves be considered to have been caused by the economic events preceding them. On this interpretation, what we have interpreted as changes in the regime were really only the realization of events and human responses under a single. more complicated regime. This more complicated regime would have to be described in a considerably more involved and "state contingent" way than the simple regimes we have described. I believe that the data of this paper could be described using this view, but that it would substantially complicate the language and require extensive qualifications without altering the main practical implications.
