## The Integrated Macroeconomic Accounts of the United States

Marco Cagetti, Elizabeth Ball Holmquist, Lisa Lynn,  
Susan Hume McIntosh, and David Wasshausen

---

The integrated macroeconomic accounts (IMAs), produced jointly by the Bureau of Economic Analysis (BEA) and the Federal Reserve Board (FRB), present a sequence of accounts that relate income, saving, investment in real and financial assets, and asset revaluations to changes in net worth. In this chapter we first provide some background information on the IMAs and on their construction. Next, we discuss the usefulness of the IMAs, focusing for instance on the evolution of household net worth and its components, a set of series that has appeared frequently in discussions of the causes and effects of the recent financial crisis. We also discuss some of the challenges associated with integrating nonfinancial and financial data sources; that is, the current and capital accounts statistics from the BEA's National Income and Product Accounts (NIPAs) and the financial statistics from the FRB's financial accounts (FAs), previously called the Flow of Funds Accounts. In the final section, we discuss future plans for improving the IMAs, including a proposed framework and methodology for breaking the financial business

Marco Cagetti is senior economist in the Division of Research and Statistics at the Board of Governors of the Federal Reserve System. Elizabeth Ball Holmquist is a financial analyst in the Division of Research and Statistics at the Board of Governors of the Federal Reserve System. Lisa Lynn is an economist in the National Income and Wealth Division of the Bureau of Economic Analysis, US Department of Commerce. Susan Hume McIntosh is senior economist in the Division of Research and Statistics at the Board of Governors of the Federal Reserve System. David Wasshausen is chief of the Industry Sector Division of the Bureau of Economic Analysis, US Department of Commerce.

We would like to thank Joshua Gallin, Dale Jorgenson, Kurt Kunze, Brent Moulton, and Kimberly Zieschang for comments and suggestions. The views expressed herein are those of the authors and do not necessarily reflect the view of the Board of Governors, the Federal Reserve System, or the Bureau of Economic Analysis. For acknowledgments, sources of research support, and disclosure of the authors' material financial relationships, if any, please see <http://www.nber.org/chapters/c12834.ack>.

sector into three subsectors: (a) central bank, (b) insurance and pension funds, and (c) other financial business.

## 10.1 Background and Evolution

The integrated macroeconomic accounts (IMAs) were developed as part of an interagency effort to further harmonize the Bureau of Economic Analysis's (BEA) National Income and Product Accounts (NIPAs) and the Federal Reserve Board's (FRB) financial accounts (FAs). Work began on these accounts in 2002 and the first version of the tables was presented at the National Bureau of Economic Research (NBER) Conference on Research in Income and Wealth's "Architecture for the National Accounts" in April 2004, with annual data for 1985 to 2002.<sup>1</sup> A February 2007 *Survey of Current Business* article officially introduced the regular production of the IMAs.<sup>2</sup> The System of National Accounts (SNA 1993) was used as the organizing framework in an effort to bring these accounts into closer accordance with international guidelines. While the resultant set of IMAs are largely in accordance with the SNA, there remain differences, particularly with respect to the way sectors are defined. The IMAs use a consistent set of sectors throughout the entire sequence of accounts, and these sectors are primarily based on definitions used in either the NIPAs or FAs. In the SNA, institutions are grouped into five mutually exclusive sectors: (a) nonfinancial corporations, (b) financial corporations, (c) general government, (d) nonprofit institutions serving households (NPISH), and (e) households. In the IMAs, estimates are calculated and presented for the following seven, mutually exclusive sectors: (a) households and NPISH, (b) nonfinancial noncorporate business, (c) non-financial corporate business, (d) financial business, (e) federal government, (f) state and local government, and (g) rest of world. The primary difference is in the treatment of noncorporate business (which includes entities such as sole proprietorships, general partnerships, limited liability partnerships, and government enterprises), which, with the exception of government enterprises, are classified as either nonfinancial noncorporate business or financial business in the IMAs. Government enterprise activities are reflected in the government sectors within the IMAs. In contrast, in the SNA, limited liability companies, limited partnerships, and government enterprises are classified as "quasi-corporations" in the financial or nonfinancial corporate sectors, and general partnerships and sole proprietorships are classified in the household sector.

Most of the IMA series are derived from published NIPA and FA data. Current account and capital account statistics are based on NIPA data, while the financial account statistics are based on FA data. The other changes

1. See Teplin et al. (2006).

2. For more information, see Bond et al. (2007).

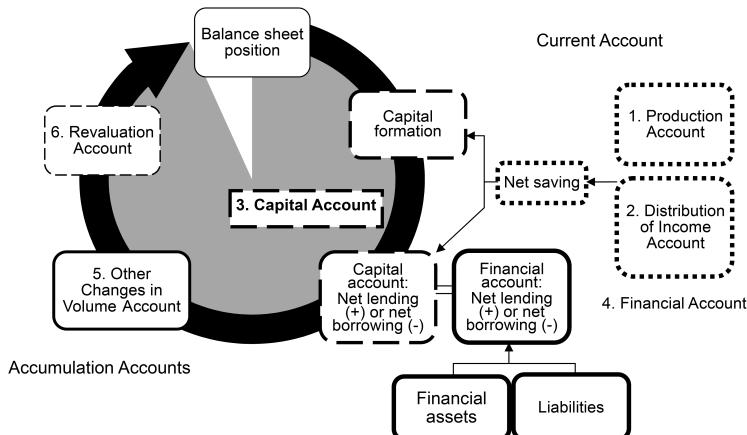

in volume, revaluation, and balance sheet accounts reflect a combination of both BEA and FA data. The BEA provides the FRB with unpublished data, where necessary, and the FRB is responsible for compiling the full set of integrated accounts. The IMAs are updated quarterly about seventy-five days after the end of the quarter and are published by both the BEA and FRB. The BEA-supplied statistics for the most recent quarter typically reflect revisions to the previous quarter, with more substantial historical revisions stemming from the NIPA annual revision introduced with each September IMA release. The FRB-supplied statistics are not constrained by a set revision cycle and thus are open to historical revisions with each quarterly update.

Since initial publication of the IMAs in 2007, there have been several improvements implemented into these accounts. One of the more important improvements was the introduction in June 2010 of quarterly IMA statistics, beginning with 1992. In June 2012, those quarterly statistics were carried back to 1960. Slightly less detail is available quarterly in the current account, primarily reflecting insufficient source data on gross flows of property income paid and received. Another recent improvement is the introduction of farmland into the real estate component of the balance sheets for both corporate and noncorporate nonfinancial businesses. Estimates for farmland were developed primarily using Economic Research Service statistics, published by the United States Department of Agriculture. Later in the chapter we discuss future plans for the IMAs.

## 10.2 Construction of the Accounts

The IMAs link saving, capital accumulation, investment in financial assets, and balance sheet positions within an integrated framework with consistent definitions, classifications, and accounting conventions. Each of the seven sectors underlying the total economy has a full complement of accounts: the current account (production and distribution of income accounts), and the accumulation accounts (capital, financial, other volume changes, and revaluation accounts). These accounts allow one to trace the factors leading to changes in the net worth position on the balance sheet of each sector. As an example, in section 10.3, we will discuss the evolution of household net worth and its composition, a set of statistics that helps us understand the causes and consequences of the financial crisis.

Figure 10.1 provides a diagram of the sequence of accounts presented in the IMAs. Broadly speaking, in the first account (current account), the IMAs record production and income. Subtracting consumption from income yields net saving. From the capital account we observe if capital formation (aka investment in “real” assets) is smaller than saving, the difference is lent to other sectors using financial instruments; otherwise, the difference must be borrowed. Net lending or borrowing, therefore, link the

**Fig. 10.1** Accumulation accounts/current account

“real” and the “financial” side of the economy. The next account, the financial account, records the lending and borrowing through the various financial instruments. Finally, the balance sheet position reflects real and financial investment flows, other changes in volume (fifth account), and holding gains/losses on assets (sixth account). Next, we will walk through the accounts using both figure 10.1 and estimates for the household and NPISH sector, which can be found in table 10A.1, found in appendix A.

The first account in the IMAs is the current account. Its first component (dotted lines) is the production account, labeled number 1 in figure 10.1, which shows the contribution made by each sector toward US production, or gross value added.<sup>3</sup> Consumption of fixed capital, or economic depreciation, is subtracted from gross value added to arrive at net value added. The current account also details the components of value added, including compensation and taxes paid, and net operating surplus<sup>4</sup> (lines 3–8 in appendix A). Sources of income (such as compensation received and net interest and net dividends received) by type are also presented in the current account (lines 10–19).

The second part of the current account, the distribution of income account (labeled 2 in figure 10.1, lines 21–28 in appendix A), shows the uses of income and how the income from current production is used to finance consumption and savings. Net saving (line 28), measured as the portion of

3. The GDP for the US economy can be calculated as the sum of gross value added for all sectors, plus the statistical discrepancy.

4. Net operating surplus reflects the income earned from the production of goods and services. It is a profits-like measure that is derived as gross output from current production minus related production costs (such as intermediate inputs, employee compensation, and taxes less subsidies).

current income that is set aside rather than spent on consumption or related purposes, is derived by subtracting consumption from disposable income.

Looking at the household and NPISH sector as an example, we see that gross value added for the sector in 2010 was \$1.8 trillion (line 1). From current production, the sector earned a net income of \$10.9 trillion (line 9), and, after income is adjusted for taxes, transfers, and social contributions/benefits, the sector's disposable income totaled \$10.8 trillion (line 26). Subtracting \$10.2 trillion of consumption (line 27), the sector's net saving amounted to \$0.6 trillion (line 28).

Net saving then enters the capital account, the first in the sequence of accumulation accounts. The accumulation accounts describe the change in the sector balance sheet between its opening and closing position. There are four accumulation accounts: capital account, financial account, other changes in the volume of assets account, and revaluation account. The capital account, shown by the dashed lines and labeled number 3, records transactions linked to the net acquisition of nonfinancial assets and capital transfers involving the redistribution of wealth used for the purchase of capital. This account consists of net capital formation (gross fixed capital formation less consumption of fixed assets), net capital transfers, acquisition of nonproduced nonfinancial assets and change in private inventories (lines 29–38). Each of these estimates is derived from estimates in the NIPAs and the fixed-asset accounts published by the BEA. Net capital transfers include transactions such as disaster-related insurance benefits, estate and gift taxes, and financial stabilization payments made by the federal government. Nonproduced nonfinancial assets transactions include purchases of land, payments for drilling rights, electromagnetic spectrum proceeds, and miscellaneous international transactions. If net saving derived from the current account is smaller than capital accumulation, the sector is a net borrower, and if net saving is greater than capital accumulation, the sector is a net lender. This difference between net saving and capital accumulation is referred to as net lending (+) or net borrowing (−). As an example, in 2010, capital formation by the household and NPISH sector amounted to about \$0.1 trillion. Since its saving was \$0.6 trillion, the sector lent \$0.5 trillion to the other sectors.

An alternate version of net lending/net borrowing (or NLNB) can be calculated from the financial account, shown in solid-lined boxes and labeled number 4 (in figure 10.1), by subtracting the net increase in liabilities (lines 70–80) from the net acquisition of financial assets (lines 40–69). In principle, the capital account and financial account measures of net lending/net borrowing should be the same, because saving that is not spent on purchases of fixed assets results in the acquisition of financial assets and borrowing that is used to finance the purchase of fixed assets results in the incurrence of financial liabilities. However, when compiling NLNB from the capital and financial accounts, the values for the two measures are almost never equal

because of differences in source data, timing of recorded flows, and other statistical differences between data used to create the measures. To reconcile the two measures, the difference between NLNB derived from the two methods (that is, line 81 minus line 38) is included as a statistical discrepancy in the other changes in volume account.

Looking again at 2010, the household sector acquired \$0.5 trillion of financial assets and decreased its liabilities by repaying about \$0.2 trillion, resulting in a net lending of \$0.8 trillion. Since the net lending obtained from the capital account amounted to about \$0.6 trillion, there is a statistical discrepancy of about \$0.2 trillion.

The other changes in volume account, labeled number 5, records the effect of exceptional events that cause either the value or volume of assets and liabilities to vary (lines 82–86). Included here are adjustments in classification and structure due to changes in data sources or calculations, disaster losses, nonproduced nonfinancial assets, and the statistical discrepancy described above. Disasters are generally defined as catastrophic events (such as hurricanes and earthquakes) with property losses exceeding 0.1 percent of GDP (which is currently about \$15 billion). Nonproduced nonfinancial assets are included since they are not recorded on the balance sheet but are included in the capital account.

The last accumulation account is the revaluation account, labeled number 6, which records holding gains and losses stemming from changes in prices since the opening balance sheet position (lines 87–97). Typically, holding gains and losses account for most of the change in net worth on the balance sheet. One major difference between the SNA and the IMA tables is that debt securities (such as corporate bonds) are shown at book value rather than market value in the IMAs, and are therefore not shown in the revaluation account.<sup>5</sup>

The closing balance sheet position is equal to the opening balance sheet position plus the changes recorded in the accumulation accounts, which are shown on the circle in figure 10.1, and are equal to the change in net worth for the sector. In the IMAs, we have chosen to use NLNB as calculated from the capital account rather than the version calculated from the financial account, and, as mentioned above, the difference between the two measures (the statistical discrepancy) is recorded in the other volume changes account to be consistent with the balance sheet data.

Returning to our example, household sector net worth was \$55.6 trillion at the end of 2009. In 2010, the sector saved \$0.6 trillion (as measured by net savings in the capital account, line 28) and gained \$2.6 trillion from changes in the prices of its assets (line 97). Net worth at the end of 2010 was \$59.1 trillion, with other changes in volume adding \$0.3 billion.

5. This convention was adopted early on at the beginning of the development of the FA. We are currently working to fill in this gap, or estimate this value, to conform with SNA guidelines.

One point of note is that, for the household and nonfinancial business sectors, the balance sheet shows FA estimates of the market value of real estate. These estimates are calculated using real estate price indices and net investment from the BEA. For the financial business and government sectors, only the current-cost net stock of structures is shown because there are no reliable estimates for the market value of real estate. All balance sheets for domestic sectors show the current-cost net stock of equipment and software. For those sectors where total real estate is reported, it may be tempting to impute a value for land as the difference between the value of real estate and current-cost net stock of structures; this practice is not recommended, however, because the two measures are estimated independently and rely on different source data. For example, for the nonfinancial corporate business sector, the difference between real estate and net stock of structures is slightly greater than zero in 2009, suggesting that the value of land owned by this sector in 2009 was negligible. Nevertheless, it is useful to analyze and question the relationship between real estate and structures in order to better understand the underlying source data and methods used to construct these statistics.

### 10.3 Uses of the IMAs

The recent financial crisis has vividly shown that analyzing the change in net worth and its composition is critical to understanding the health, risks, and prospects of an economic sector. Net worth is a broad measure of the wealth of a sector, often used in conjunction with other variables, such as income and interest rates, to study variables such as consumption and saving. The IMAs enable one to analyze net worth and its composition, clarifying how the current balance sheet position came about by distinguishing between saving, borrowing, holding gains or losses, and other changes in volume.

As an example, we can look at household and NPISH sectors in the IMAs. In the first half of the last decade, the household sector shifted from being a major lender to a major borrower (table 10.1, line 2), rivaled only as a borrower by the federal government sector (line 6). It was at this same time that the rest of the world sector (line 8) became the predominant lending sector.

At the same time, household net worth surged rapidly and the ratio of household net worth to disposable personal income reached record levels (figure 10.2). This increase was caused not by elevated saving, but by sizable capital gains both on housing wealth and on stock-market wealth (figure 10.3).

Indeed, the ratio of both housing wealth and stock market wealth to disposable personal income surged to historically unprecedented levels (figure 10.4). Not surprisingly, household debt also ballooned. The ratio of household debt to disposable personal income increased from around

90 percent at the beginning of the decade to an all-time high of around 130 percent in the middle of 2007 (figure 10.5).

This ratio dropped to 111 percent by the end of 2011 as consumers borrowed less and as a significant amount of mortgage debt was written off. As can be seen in table 10.1, line 2, the household sector shifted back to being a major net lender in 2008.

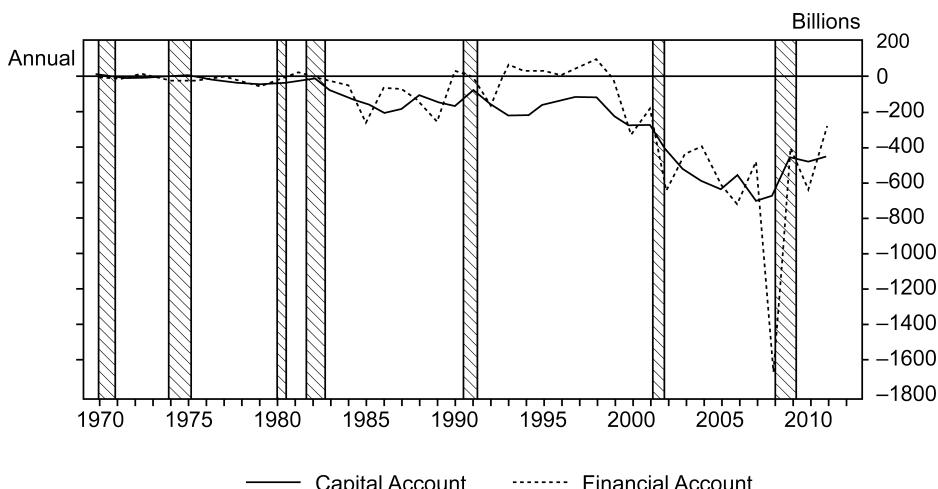

Net borrowing by the federal government (table 10.1, line 6), on the other hand, ballooned to over \$1.3 trillion in both 2009 and 2010. In 2009, the rest of the world sector (line 8) was a significant lender, along with the financial business sector (line 5). The nonfinancial corporate business sector (line 4), traditionally a net borrower, became a net lender in 2009, as capital expenditures remained relatively low and retained earnings elevated.

#### 10.4 Challenges in Linking Current, Capital, and Financial Accounts

One innovative feature of the integrated accounts is the ability to compare net lending/net borrowing calculated from the capital account with the alternative measure calculated from the financial account. As discussed above, in the capital account measure, a sector's net lending or net borrowing is the difference between its net saving (disposable income less current spending) and its net investment (gross purchases of "physical" capital less depreciation on its existing capital stock). In the financial account measure, a sector's net lending/net borrowing is the difference between its net acquisition of financial assets and its net increase in liabilities. Thus, except

for statistical discrepancies, the two measures of a sector's net lending/net borrowing should be the same.

Figure 10.6 compares the capital account total net lending or net borrowing for all domestic sectors (the black line) with the financial account measure (the dotted line). The two lines are very close to each other and hover around zero until about 1980. From that point forward, the United States becomes an increasingly larger net borrower vis-à-vis the rest of the world. The two measures of net lending/net borrowing remain fairly similar, although the financial account measure is more volatile, until around 2008, the year of the financial crisis, when the two lines diverge sharply. This divergence could be partly due to data sources subject to historical benchmark revisions, but is more likely due to data gaps in the financial accounts. These data gaps could reflect off-balance sheet data that have not been captured completely, such as derivatives, or transactions taking place at a level of business structure not currently included in any sector in the accounts, such as nonfinancial holding companies. Also, the treatment of intangibles in the capital and financial accounts could be inconsistent. These data gaps and differences were probably more significant during the financial crisis, and perhaps unsurprisingly, when you compare the two measures of net lending/net borrowing by sector, as shown in table 10.1, the greatest differences appear to be for the nonfinancial corporate business sector (line 4) and the financial business sector (line 5). In 2009, the two measures of total NLNB

**Fig. 10.6** Net lending (+) or net borrowing (–) in the capital and financial accounts

Source: Integrated macroeconomic accounts, June 7, 2012.

Note: Bars indicate NBER recession periods.

(figure 10.6) moved closer together as the economy showed some improvement and have maintained a similar pattern in the most recent years.

Additional issues in comparing the capital account and financial account measures of net lending/net borrowing by sector could be due to the different treatment of debt charge-offs, as well as company- versus establishment-based statistics.

In the financial accounts, debt charge-offs are a component of NLNB, rather than of other changes in volume accounts, as suggested by the SNA.<sup>6</sup> That is, if debt is charged off, net acquisition of assets falls and net lending decreases for the issuing sector. In other words, charge-offs are not distinguished from repayments. However in the NIPAs, charge-offs are not part of net lending/net borrowing as they do not directly change saving or investment. Before the most recent financial crisis, mortgage debt charge-offs for the financial sector were very small.<sup>7</sup> With the financial crisis, however, charge-off rates increased rapidly from a few basis points to more than two percent as many houses entered foreclosure.<sup>8</sup> Because the mortgage loans (an asset) are generally held by financial institutions and the corresponding mortgage debt is held by primarily by nonfinancial sectors, in particular households, charge-offs generate a discrepancy between the respective sectors' net lending and borrowing computed from the capital and financial accounts. Figure 10.7 shows a rough measure of charge-offs for both residential and commercial mortgages (the dashed line) exploding in 2008, which helps to explain the discrepancy in net lending/net borrowing beginning in 2008 (the distance between the solid and the dotted line).<sup>9</sup>

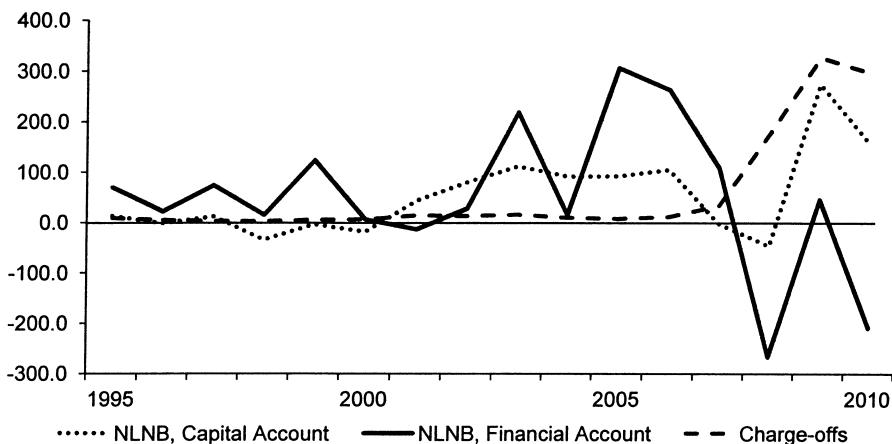

Finally, in the capital accounts, net lending/net borrowing reflects a mix of company- and establishment-based statistics, while net lending/borrowing from the financial accounts primarily reflects institutional-based reporting. The NIPA measures of profits and interest are derived primarily from IRS tabulations of business tax returns, which are reported on a consolidated basis. Therefore, financial activities of captive finance companies (a subsidiary whose purpose is to provide financing to customers buying the parent company's product) are not reflected in the profits of the financial sector. Unfortunately, this is not an easily remedied issue. The BEA is actively work-

6. This convention is due to lack of data on all types of loans. While data on charge-offs on loans at banks exists, there is currently no official measure of charge-offs on securitized loans, which comprise the majority of mortgage debt in the United States.

7. A precise series for charge-offs on debt held by financial institutions does not exist. In chart 6 we approximate the value of charge-offs on mortgage debt by applying the charge-off rate on mortgages held at banks to the total amount of outstanding mortgages. This is a rough approximation because the charge-off rate on mortgages held in pools could be different, and because we do not distinguish mortgages held by the financial sector from mortgages held by other sectors.

8. We thank Jim Kennedy and Maria Perozek for the analysis of the effects of charge-offs on the saving rate.

9. The charge-off measure is just a rough approximation based on the charge-off rates for mortgages held at banks.

ing with IRS to identify and obtain additional information on the activities of subsidiaries, which should enable us to better understand the financial sector.<sup>10</sup>

## 10.5 Future Plans

### 10.5.1 Subsectoring Finance

Following the financial crisis that began in 2008, members of the G-20 established the G-20 Data Gaps Initiative in an attempt to improve global financial statistics, potentially helping policymakers and market participants identify and address stresses in the financial system before another crisis occurs. One of the conclusions drawn was that sectoral data matter, and emphasis was placed on producing (and publishing) subsector detail for the financial sector. Specifically, one of the recommendations was “to develop a strategy to promote the compilation and dissemination of the balance sheet approach (BSA), flow of funds, and sectoral data more generally.” In February 2011, the IMF and OECD jointly organized a conference, “Strengthening Sectoral Position and Flow Data in the Macroeconomic Accounts.” The following four financial subsectors, including their corresponding North American Industrial Classification System (NAICS) code, were proposed: (a) central bank (521), (b) other deposit-taking institutions (5221), (c) insur-

10. In the BEAs annual industry accounts (AIA), NIPA profits are converting from a company to an establishment basis primarily using employment data from the Economic Census. Obtaining additional information on subsidiaries from the IRS would potentially improve the AIA estimates as well.

ance and pension funds (524 + 525110), and (d) other financial business (remaining 52 and 55). The IMAs provide an excellent framework to address data gaps in the national accounts of a country and expanding the IMAs to include these additional tables should help analysts better evaluate the risk characteristics of different types of financial institutions.

While sufficient data exist to meet the subsectoring recommendations for the financial account, the current and capital accounts present a challenge. The BEA and FRB initially attempted to follow the recommended subsectoring in the IMAs; however, we eventually concluded that there were insufficient data in IRS tax return-based estimates to accurately identify “other deposit-taking institutions” from “other financial business.” Specifically, the consolidated IRS tax return-based statistics for bank holding companies (NAICS 551111—mapped to “other financial business”) include significant activity for subsidiaries classified as “other deposit-taking institutions” (NAICS 5221). To better understand the magnitude of activity of depository subsidiaries reported in IRS statistics as bank holding companies, the BEA received a sample of bank holding company subsidiary data from 2010 preliminary IRS statistics. Our sample suggested that for 2010, within corporate bank holding companies, approximately 40 percent of receipts, 60 percent of interest received, and 20 percent of dividends received were attributable to subsidiaries associated with “other depository taking institutions,” rather than “other financial business.”

As mentioned in section 10.4 above, the nature of the company-based statistics presents some challenges for us and we are actively researching ways to address this. An additional challenge we faced with accommodating the proposed subsectors is that the NIPA industry-based estimates do not always contain sufficient NAICS detail. For example, the subsector “insurance and pension funds” reflects the sum of NAICS 524 (insurance) and NAICS 525110 (pension funds), however separate estimates for NAICS 525110 do not exist in the NIPAs.

As a first step toward completing this financial subsectoring in the IMAs, we are proposing to combine “other deposit taking corporations” with “other financial business.” Even with combining two of the four subsectors, a number of assumptions are needed in order to derive the remaining subsectors. Nevertheless, publishing these additional tables should help analysts better evaluate the risk characteristics of different types of financial institutions. It should be noted that, with the exception of property income flows associated with government pensions, IMA estimates for total financial business presented in the currently published tables are unaffected by this proposal. It should also be emphasized that estimates presented for the subsectors are extremely preliminary and subject to change. Emphasis instead should be placed on the framework and methodologies described herein. The following sections briefly describe how each of the subsectors will be constructed. Draft tables for the financial business subsectors can be found in appendix B.

*Central Bank (Table 10B.2)*

The central bank, for purposes of the IMAs, is essentially defined as the Federal Reserve. The Federal Reserve is separately recognized under NAICS 521 and underlying detail already exists for many of the IMA series in the current, capital, financial, and balance sheet accounts. The NIPA estimates for Federal Reserve (which underlie capital and current account data for this subsector) rely heavily on the Federal Reserve annual report as a primary data source, and include both the Federal Reserve Banks and the Federal Reserve Board. In this sector, gross value added is estimated from unpublished statistics from the BEAs annual industry accounts (AIAs). For this specific industry/subsector, there is no distinction between company versus establishment so using AIA (establishment-based) in lieu of an indirectly derived NIPA (mostly company-based) estimate is not problematic. Compensation estimates are derived from unpublished NIPA detail, which are consistent with the AIA estimates. There are several series within the current and capital accounts for which no data are available (such as other current transfers and reinvested earnings on FDI abroad), and in these cases we have assumed that the values are zero. The net operating surplus (NOS) is derived residually.

In the financial accounts, the central bank subsector is defined as the monetary authority; that is, the assets and liabilities of the Federal Reserve Banks and the Treasury monetary accounts that supply or absorb bank reserves.<sup>11</sup> For the financial accounts, the data come from the Federal Reserve statistical release H.4.1, Factors Affecting Reserve Balances. It is worth noting that the net lending/net borrowing series shown for the central bank is somewhat confusing because of the way central bank operations appear in the accounts (for instance, currency and deposits are a liability of the central bank). However, looking separately at the assets and liabilities, both in the financial accounts and in the balance sheet, can help to understand the behavior of the central bank. For example, the loans extended to financial institutions in 2008 and the operations related to the quantitative easing policies since the crisis are reflected in the sharp increase in the central bank's assets.

*Insurance and Pension Funds (Table 10B.3)*

The insurance and pension fund subsector is defined as the NAICS insurance industry (524) plus pension fund industry (NAICS 525110). Within the current and capital accounts, estimating the insurance portion of this subsector is fairly straightforward because NIPA estimates for this industry currently exist and, in many cases, are published. Unfortunately, that is not

11. The Federal Reserve System includes the twelve Federal Reserve Banks and the Board of Governors of the Federal Reserve System in Washington, DC. Essentially all of the accounts of the monetary authority sectors are held at the Federal Reserve Banks, not at the Board of Governors. Technically, the monetary authority sector in the financial accounts excludes the Board of Governors.

the case with pension funds, as very little information currently exists in the NIPAs for this industry. Fortunately, most of the current and capital account series for pension funds are fairly small, with the exception of interest and dividends, which flow through pension funds into the household sector. Accordingly, we have assumed these small series, with no source data, are zero for pension funds and therefore only the receipts and payments of property income associated with pension funds are reflected in this subsector. Because these transactions pass through this subsector, there is no impact on net lending/net borrowing. Estimates for these flows were derived using data from multiple sources, but rely most heavily on statistics published in the FAs (for pension asset compositions and interest rates), annual reports for federal government retirement funds, IRS Form 5500 data, and statistics published in the Census Bureau Survey of Public-Employee Retirement Systems.<sup>12</sup>

In this proposal, we are including property income associated with both defined benefit and defined contribution plans.<sup>13</sup> It is debatable whether or not property income associated with defined contribution plans should be reflected in this account at all, since the property income is considered to be owned directly by the household sector. Nevertheless, we thought it would be helpful to the users of these accounts to see the effect of both types of pension plans. Moreover, the financial accounts for this subsector, discussed next, reflect both defined benefit and defined contributions plans.

In the financial accounts, the insurance sector is based on reports filed to insurance authorities. Of note, it does not include most insurance holding companies. For pensions, the financial account also reflects both defined benefit and defined contribution plans.

Looking at table 10B.3 in the appendix, which shows preliminary estimates for the subsector, we can see that the industry's share of gross value added is approximately 1/3 of that of the total financial sector. Operating surplus (table 10B.3, line 10), which is a profits-like measure that excludes income from interest and dividends, rebounded for the subsector in 2010, and was almost twice 2008 levels. In general, both the financial and capital accounts indicate that this subsector has been a net lender to the economy (figure 10.8).

#### *Other Financial Business (Including Other Deposit-Taking Corporations, Table 10B.4)*

The other financial business subsector is calculated residually as total financial business (as shown in table 10B.4) less the insurance and pension

12. We thank Marshall Reinsdorf for helpful comments regarding the treatment of pensions in the National Income and Product Accounts. We also thank David Lenz, Dylan Rassier, and Benyam Tsehaye for providing estimates of pension-related dividends and interest.

13. Property income flows associated with government-defined contribution plans were not available and therefore not reflected in the accompanying tables.

subsector, and less the central bank subsector. This subsector implicitly includes estimates for credit intermediaries, security brokerages, investment pools, other deposit-taking corporations, and financial holding companies.

Preliminary estimates show that other financial business accounts for approximately 2/3 of production for the financial sector. Looking at preliminary net lending/net borrowing for the sector (figure 10.9), financial NLNB is much more volatile than the corresponding measure in the capital account. There has also been a discrepancy between capital and financial

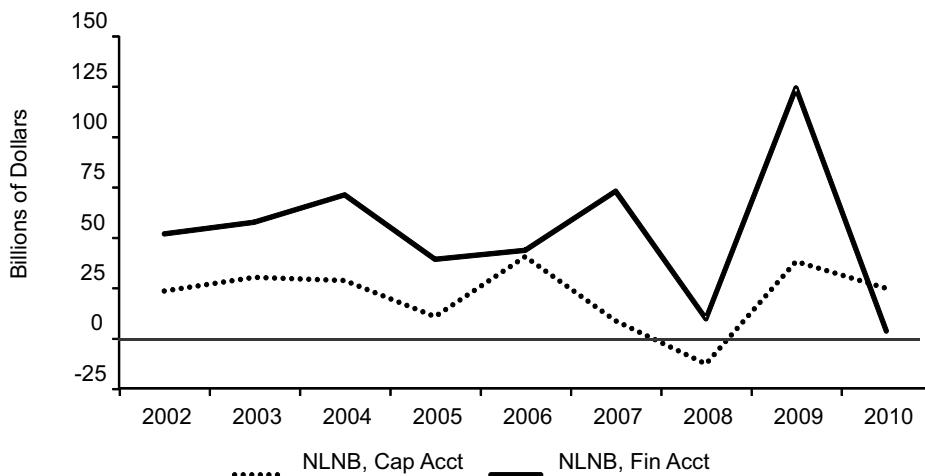

Fig. 10.8 Net lending/net borrowing, pension and insurance subsector

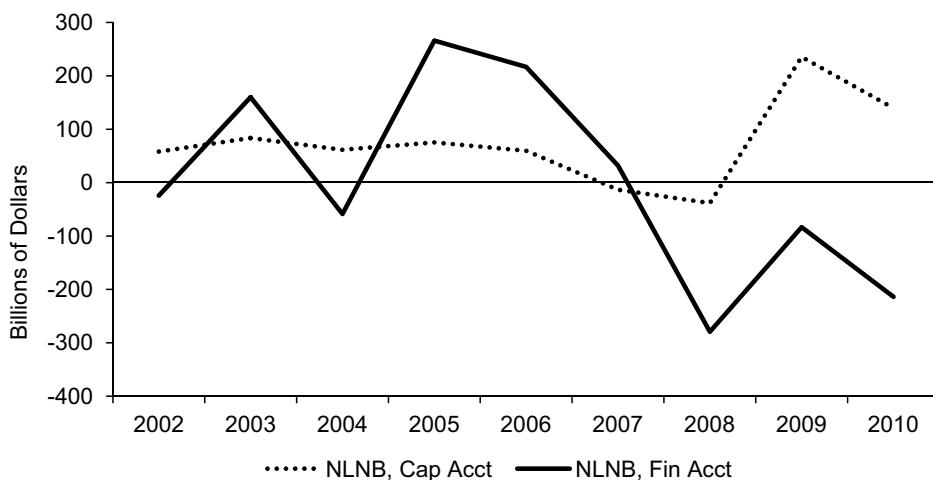

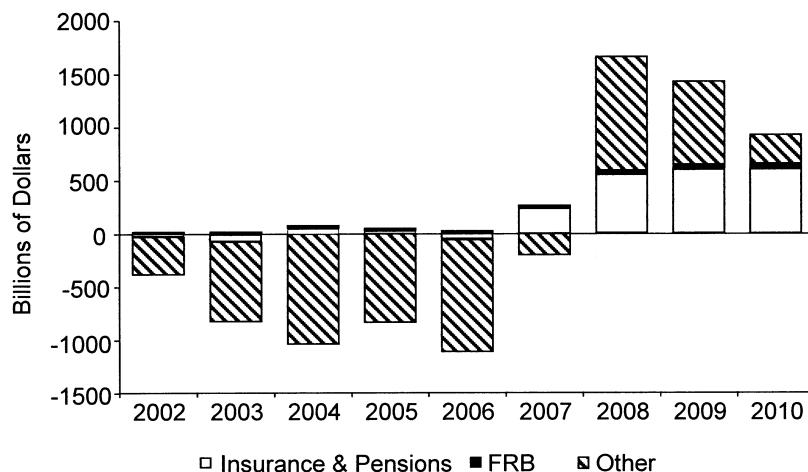

Fig. 10.9 Net lending/net borrowing, other financial business

**Fig. 10.10 Financial subsector net worth (in billions of dollars)**

accounts since 2008, which can be in part explained by the treatment of charge-offs, as explained in section 10.4.

#### *Brief Observations Relating to Proposed Financial Subsector Data*

In interpreting the financial sector tables, it is important to highlight a few issues in the construction of net worth. As for all other sectors, net worth is the difference between assets and liabilities. The SNA guidelines suggest to treat the market value of the outstanding shares issued by a corporation as a liability for the sector. Therefore, other things equal, declines in stock prices will cause an increase in the net worth of the sector, which complicates the interpretation of the net worth measure for the financial sectors (which are mostly comprised by corporations), as well as for the nonfinancial corporate sector. As shown in figure 10.10, the large increases in net worth in 2007 and 2008 can be explained by the large decline in financial stock prices during the crisis, and should obviously not be interpreted as an increase in the value of these companies. Rather, one should exclude equity capital from possible balance-sheet based measure of firm value.

In addition, at the moment, our measure of net worth does not include the market value of real estate held by financial companies.<sup>14</sup> As a result, our financial balance sheets do not capture the large declines in commercial real estate during the crisis.

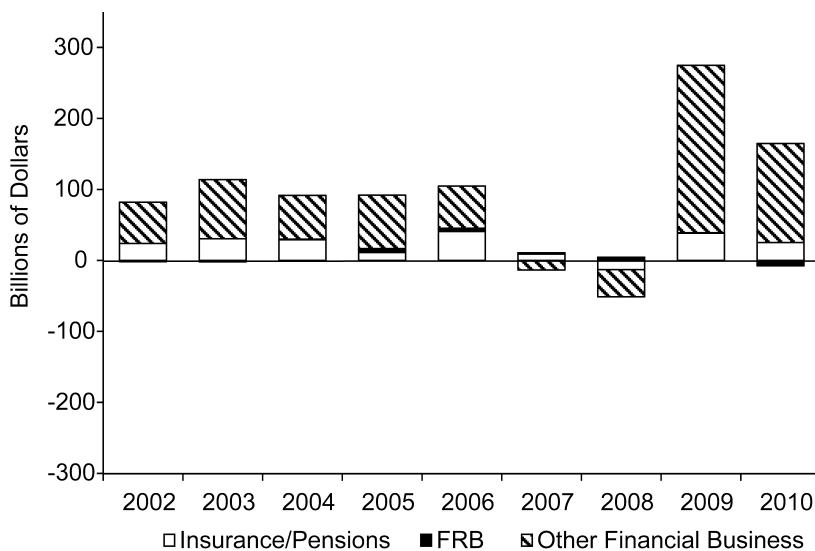

It is also interesting to point out a few facts about net lending/net bor-

14. The market value of real estate held by nonfinancial businesses is instead recorded in the nonfinancial corporate and noncorporate business accounts.

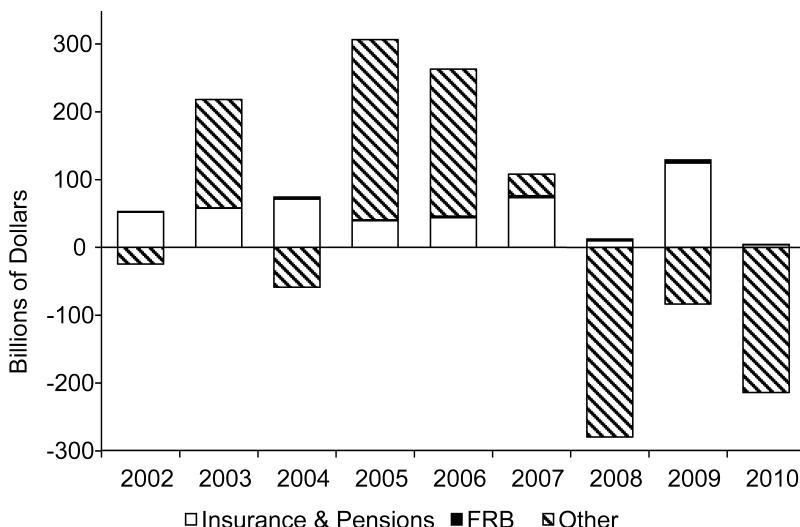

rowing of the financial sectors. Usually both the capital account and the financial account indicate that the pension and insurance subsector is a net lender for each year. There is a greater divergence in net lending/net borrowing trends for the other financial business subsector; in this subsector, NLNB for the financial account is much more volatile, with the lending and borrowing amounts much greater than in the capital account. As mentioned in sections above, conceptually the two measures should match, but disparities can arise due to differences in timing, source data, and other statistical differences. This subsector includes a wide variety of institutions with different risk exposures and cyclical behaviors, and different portfolio composition, which could help explain the larger volatility of NLNB in the financial accounts. Separating the various types of institutions within the subsectors will be helpful in understanding the behavior of the series and the discrepancy between financial and capital accounts. A comparison of net lending/net borrowing for the subsectors can be found below in figures 10.11 and 10.12.

#### 10.5.2. Other Future Developments

A current drawback of the IMAs, as pointed out by Palumbo and Parker (2009) and by Eichner, Kohn, and Palumbo (2010), is that the accounts did not show the increased exposure of the financial business sector to house price risk because of the aggregation of the sector and of certain asset classes. As discussed earlier, the sector consolidation masked how lever-

**Fig. 10.11** Net lending/net borrowing—capital account

**Fig. 10.12** Net lending/net borrowing—financial account

aged some of the financial subsectors had become. In addition, structured financial products and traditional corporate bonds and commercial paper, which are group together as “debt securities” in the IMA, have very different risk characteristics. To address this drawback, we are examining the feasibility of separating the holdings of structured products from traditional debt instruments.

In addition to presenting additional detail for the financial business sector, we are also investigating the possibility of presenting households separately from nonprofit institutions serving households. These two sectors have notably different characteristics from one another and being able to analyze them separately would be helpful.<sup>15</sup> We would also like to incorporate real estate values into the balance sheets for the financial and government sectors. Incorporating conservative estimates may be an improvement over assuming the value is zero.

In addition to these longer term projects, we believe there are a number of useful series and ratios (constructed from currently published IMA statistics) that could be explicitly added to the addenda of the IMAs. For example, in the household and nonprofit institutions serving households sector, the ratio of real estate to disposable income quickly reveals the housing “bubble”

15. Here, the primary challenge for the financial accounts is that most data for nonprofit institutions is obtained from tax return-based data, which does not allow us to precisely identify the different financial instruments required to make this split.

that peaked in the mid 2000s. Another useful ratio might be the value of corporate equities to disposable income for households and institutions, which peaked in 1999 and then fell rapidly. A useful series that could be added to the household and institutions sector is household net worth from the FRB's Survey of Consumer Finances (SCF). A quick comparison showed household net worth measured indirectly in the IMAs tracks very well the mean household net worth measured directly in the SCF—an important validation for both sets of estimates.<sup>16</sup> For the financial business sector, including selected estimates from the BEA's AIAs might also be useful for comparison purposes. Including these types of related statistics can provide an important validity check and serves to further integrate economic accounts.

The IMAs have already proven to be valuable in studying the US economy. The Federal Reserve and BEA will continue to work together to improve the presentation and data availability of these accounts so that in the future policymakers will be better able to see shifts in the financial climate of the United States prior to business cycle expansions and contractions.

16. The SCF is a triennial interview survey of US families, sponsored by the Board of Governors of the Federal Reserve System with the cooperation of the US Department of the Treasury. For more information see: <http://www.federalreserve.gov/Pubs/Bulletin/2012/articles/scf/scf.htm>. For a comparison of the net worth estimates implied by the two data sets, see Alice Henriques and Joanne Hsu (chapter 9, this volume).

Source: SNA tables, June 7, 2012.

Notes: Quarterly figures are seasonally adjusted annual rates. NPISHs = nonprofit institutions serving households.

<sup>a</sup>Consists of rental income of tenant-occupied housing and proprietors' income. Quasi-corporations are unincorporated enterprises that function as if they were corporations; they primarily cover their operating costs through sales, and they keep a complete set of financial records.

<sup>b</sup>Government-sponsored enterprises (GSEs) consist of Federal Home Loan Banks, Fannie Mae, Freddie Mac, Federal Agricultural Mortgage Corporation, Farm Credit System, the Financing Corporation, and the Resolution Funding Corporation, and they included the Student Loan Marketing Association until it was fully privatized in the fourth quarter of 2004.

<sup>c</sup>Funds invested by financial institutions such as domestic hedge funds through the Public-Private Investment Program (PPIP).

<sup>d</sup>The statistical discrepancy is the difference between net lending or net borrowing derived in the capital account and the same concept derived in the financial account. The discrepancy reflects differences in source data, timing of recorded flows, and other statistical differences between the capital and financial accounts.

<sup>e</sup>Not elsewhere classified.

<sup>a</sup>Consists of rental income of tenant-occupied housing and proprietors' income. Quasi-corporations are unincorporated enterprises that function as if they were corporations; they primarily cover their operating costs through sales, and they keep a complete set of financial records.

<sup>b</sup>Government-sponsored enterprises (GSEs) consist of Federal Home Loan Banks, Fannie Mae, Freddie Mac, Federal Agricultural Mortgage Corporation, Farm Credit System, the Financing Corporation, and the Resolution Funding Corporation, and they included the Student Loan Marketing Association until it was fully privatized in the fourth quarter of 2004.

<sup>c</sup>The statistical discrepancy is the difference between net lending or net borrowing derived in the capital account and the same concept derived in the financial account. The discrepancy reflects differences in source data, timing of recorded flows, and other statistical differences between the capital and financial accounts.

<sup>d</sup>Excludes land. Includes corporate and noncorporate financial business.

<sup>a</sup>Consists of rental income of tenant-occupied housing and proprietors' income. Quasi-corporations are unincorporated enterprises that function as if they were corporations; they primarily cover their operating costs through sales, and they keep a complete set of financial records.

<sup>b</sup>Government-sponsored enterprises (GSEs) consist of Federal Home Loan Banks, Fannie Mae, Freddie Mac, Federal Agricultural Mortgage Corporation, Farm Credit System, the Financing Corporation, and the Resolution Funding Corporation, and they included the Student Loan Marketing Association until it was fully privatized in the fourth quarter of 2004.

<sup>c</sup>The statistical discrepancy is the difference between net lending or net borrowing derived in the capital account and the same concept derived in the financial account. The discrepancy reflects differences in source data, timing of recorded flows, and other statistical differences between the capital and financial accounts.

<sup>d</sup>Excludes land. Includes corporate and noncorporate financial business.

<sup>a</sup>Consists of rental income of tenant-occupied housing and proprietors' income. Quasi-corporations are unincorporated enterprises that function as if they were corporations; they primarily cover their operating costs through sales, and they keep a complete set of financial records.

<sup>b</sup>Government-sponsored enterprises (GSEs) consist of Federal Home Loan Banks, Fannie Mae, Freddie Mac, Federal Agricultural Mortgage Corporation, Farm Credit System, the Financing Corporation, and the Resolution Funding Corporation, and they included the Student Loan Marketing Association until it was fully privatized in the fourth quarter of 2004.

The statistical discrepancy is the difference between net lending or net borrowing derived in the capital account and the same concept derived in the financial account. The discrepancy reflects differences in source data, timing of recorded flows, and other statistical differences between the capital and financial accounts.

<sup>d</sup>Excludes land. Includes corporate and noncorporate financial business.

<sup>a</sup>Consists of rental income of tenant-occupied housing and proprietors' income. Quasi-corporations are unincorporated enterprises that function as if they were corporations; they primarily cover their operating costs through sales, and they keep a complete set of financial records.

<sup>b</sup>Government-sponsored enterprises (GSEs) consist of Federal Home Loan Banks, Fannie Mae, Freddie Mac, Federal Agricultural Mortgage Corporation, Farm Credit System, the Financing Corporation, and the Resolution Funding Corporation, and they included the Student Loan Marketing Association until it was fully privatized in the fourth quarter of 2004.

<sup>c</sup>The statistical discrepancy is the difference between net lending or net borrowing derived in the capital account and the same concept derived in the financial account. The discrepancy reflects differences in source data, timing of recorded flows, and other statistical differences between the capital and financial accounts.

<sup>d</sup>Excludes land. Includes corporate and noncorporate financial business.
