Is the Decline in the Number of Community Banks Detrimental to Community Economic Development?

Bernadette Minton, Alvaro G. Taboada, and Rohan Williamson

NBER Working Paper No. 32521

May 2024

JEL No. G2,G20,G21,G28

ABSTRACT

Our research examines the impact of dwindling community bank numbers on community investment and economic development. Initially, we confirm the vital role of community banks' small business lending in local development. Contrary to popular belief, we find that a decrease in community banks positively affects community investment, through small business loan (SBL) originations. Key factors include the local presence of other community banks and the continuity of the consolidating bank's presence. Interestingly, the effect remains neutral in underserved or distressed counties and diminishes when a large bank acquires a community bank without maintaining a local presence. Post-consolidation, community banks emerge larger and more robust, capable of issuing larger SBLs, while larger banks and Fintech firms contribute by providing smaller SBLs. Overall, our findings reinforce the critical contribution of community banks to local development, suggesting that a reduction in their numbers leads to a stronger, more stable banking infrastructure in the small business lending landscape.

1. Introduction.

The steady decline in the number of community banks due to consolidations and failures over the past two decades has ignited a concern that the disappearance of these institutions could signify the loss of an important driver of community development (see, for example, Berger and Udell, 1995; Stein, 2002, and Levine, Lin, Peng, and Xie, 2020). Community banks, which invest a higher percentage of their loan portfolio in small business lending than large banks (Berger, Kashyap, and Scalise, 1995; Strahan and Weston, 1998), have been at the leading edge of job creation and community development. As stated on the website of the Independent Community Bankers of America, (ICBA), “(c)ommunity banks are an integral part of Main Street; they reinvest local dollars back into the community and help create local jobs.” In addition, the US Small Business Administration Office noted that, “small businesses have accounted for 66 percent of employment growth over the last 25 years.”¹ The decline in the number of community banks could adversely affect small firms, which, as noted, are vital for community development. In a letter to bank regulators, the Chairman of the U.S. Senate Committee on Banking wrote “Consolidation also harms small businesses. Study after study has documented how, following bank mergers, small business lending dries up and available loans become more expensive. Consolidation among banks also supports consolidation in non-financial industries, undermining small enterprises.”²

These concerns motivate the key question explored in this study: whether the overall reduction in the number of community banks leads to a decrease in lending to small businesses, which in turn could have adverse effects on community investment and economic development. To examine this question, we first investigate the impact of small business loan (SBL) originations on community economic development, and then analyze how the loss of a community bank affects local SBL originations in counties in which the closed community bank had a physical presence (a full-service branch).

¹ [Small Business Facts: Small Business Job Creation \(sba.gov\)](https://www.sba.gov/small-business-facts)

² [Brown Urges DED and OCC to Scrutinize Bank Mergers](https://www.brown.senate.gov/newsroom/press/release/sherrod-brown-fed-occ-scrutinize-bank-mergers)
<https://www.brown.senate.gov/newsroom/press/release/sherrod-brown-fed-occ-scrutinize-bank-mergers>

The Federal Reserve generally defines community banks as banks that serve a small geographic region with assets below \$10 Billion. We adopt a similar definition, considering any bank with assets under \$10 billion (in 2019 US dollars) as a community bank and defining a community as a county. According to this criterion, there was a significant reduction of nearly 48% in community banks, from 8,361 to 4,355, between 1999 and 2019. By the end of this period, these banks constituted approximately 97% of all commercial banking institutions.

The Community Reinvestment Act (CRA) of 1977 was based on the belief that local bank investment, through lending to small businesses, will lead to community development in the local market and this is particularly important for distressed or underserved communities, see Ding, Lee and Bostic (2018). This lending focus by community banks is due to their advantage, relative to large banks, in relationship lending on which small firms rely (e.g., Berger and Udell, 1995, 2002; Berger, et al. 2005; Cole, Goldberg, and White, 2004; Berger, Bouwman and Kim, 2017). In fact, the ICBA prides themselves in the relationship banking approach which they argue are vital for overall economic growth.

We begin our analysis by examining the impact of small business loan (SBL) originations on community development. Originating loans is the mechanism through which community banks invest in small businesses, which is believed to be vital for community economic development. We use three proxies for community economic development: the annual growth in 1) Small establishments (number of firms with fewer than 50 employees); 2) Employment (the total employment in the county), and 3) Small firm employment (employment in the county by firms with fewer than 50 employees). To address endogeneity concerns, we use a Bartik-like instrumental variables as in Bartik (1991) and Blanchard and Katz (1992). The results show that the growth in small business (SB) lending is positively associated with measures of county economic development. The positive results remain in distressed and underserved counties and establish a baseline assumption that growth in SBL originations is important for community development.

Next, we directly examine the impact of the loss (closure) of a community bank on local SBL originations, measured using the CRA data for reporting banks aggregated at the county-year level along with several other data sources that provide detailed county level macro-economic data and bank level information

over the 1999 to 2019 sample period. We use a stacked difference-in-differences (DiD) regression cohort approach where the treatment group consists of counties that experience the loss (closure) of a community bank in a given year. The results show that counties that lose a community bank experience higher SBL originations after the bank's closure, relative to the control group. In additional tests, we find similar results when we include Small Business Association (SBA) 7A loans for non-CRA reporting banks to capture total SBL originations in a county.

Generally, this positive impact is not consistent with the conventional belief that the loss of a community bank will have adverse effects on community development because of small firms' reliance on community banks for financing. We next set out to investigate potential explanations for this potentially counterintuitive result.

Before developing potential explanations, we note that bank closures over past couple of decades have been steady over the sample period and are widespread nationally but there are differences in the numbers across counties (see Figure 2). We thus examine county characteristics that affect the probability of a county losing a community bank and its impact on SBL lending. This analysis shows that the likelihood of losing a community bank is lower in counties with higher deposit concentration and a higher proportion of small establishments, while counties with faster population growth, higher average wages, larger shares of deposits by the top four banks and weaker banks are more likely to lose a community bank. Additionally, closures are more likely in underserved higher community bank deposit counties but are less likely in distressed counties.

We next examine plausible explanations for this counterintuitive baseline results based on community level characteristics, bank-level decisions and the evolution of SB lending behavior. At the county/community level, we document that community bank losses lead to increases in SBL originations but only in counties with a high concentration of other community banks. For bank-level differences, when the consolidated entity is a community bank and maintains a presence in the local county, post-consolidation, there is a significant positive increase in SBL originations. However, the increase in SB lending is significantly reduced when the new consolidated entity is a large bank (assets >\$10 billion). Interestingly, we also find a significant increase in SB

lending by other community banks in the county after a community bank closure, highlighting competition as an important driver of the observed results.

To gauge the importance of changes in overall SB lending for the main results, our analysis explores the evolving SB lending practices of community banks, large banks, and the role of Fintech companies. Despite an increase in community bank sizes during the study period, their proportion of SB loans within loan portfolios has remained steady, indicating that even as they expand in size, these banks consistently support small businesses. Community banks also have started issuing larger SB loans. Meanwhile, technological advancements in lending have led large banks to increasingly focus on smaller SB loans and lending to small businesses.

In further analysis, we examine SB lending changes by the consolidated banks in the counties where these banks had the highest deposit concentration prior to closure.³ We create bank-level cohorts at the target county-consolidation year, collecting SB lending and financial data for the proforma consolidated banks (treated) and for other local banks (control) banks within a seven-year window around each consolidation event. Our findings reveal a notable post-consolidation increase in SB lending by the consolidated bank relative to the control group, especially in distressed and underserved counties and in counties with a larger concentration of other community banks. The effect is less pronounced when the consolidated entity is large. These results suggest that increased size and stability of community banks following consolidation can enhance small business lending in affected counties, challenging the concerns about the negative impact of consolidations on local SB lending.

During our sample period, the GFC affected the overall banking sector. Interestingly, we find that post-GFC, the increase in SBL originations following community bank closures is primarily driven by community banks, aligning with arguments emphasizing significant structural changes in the banking sector post-GFC that are yet to be fully understood. An emerging factor is rise in Fintech lending activity in the post-GFC period (Gopal and Schnabl, 2022). Incorporating Fintech lending presence in our analysis, despite the reduced sample size due to data constraints, shows (results not tabulated) an increase in SBL originations post-

³ The mean (median) fraction of deposits held by closed banks in their main county is 82.3% (99.9%).

community bank closure, supporting the findings by Gopal and Schnabl (2022) and highlighting the evolving landscape of SB lending.

Given the importance of community banks to the overall economy, surprisingly, there have been few papers that examine the importance of community banks on community development through the provision of capital to small firms. The existing literature has focused on large banks' importance for the overall economy, except for studies that assess the importance of Fintech lending to small firms, see Gopal and Schnabl (2022). The more recent related literature has focused on relationship lending to these firms and their potential importance, especially during a crisis, see DeYoung, Grom, Torna, and Winton (2015). There is little finance research on a very important aspect of the U.S. economy, community development. Community banks play a vital role in community development and job creation that is generally not the main focus of large banks' lending strategy. Community economic development is a key factor that drives the growth and stability of any economy. The results of this study make important contributions in the understanding of important drivers of community investment, job creation and overall economic growth. Our findings underscore the impact of community banks on local economic development through their SB lending. Furthermore, our results show that the strength and concentration of these institutions in the local community, and not their number, will drive future growth in SB loans and community development.

The paper is organized as follows. Section 2 describes the data and sample selection. Section 3 discusses the role of community banks in community economic development and the effect of losing of a community bank on county-level SB lending. Section 4 examines explanations for the rise in county-level SB lending following community bank closures. Fintech lending presence is address in both sections 3 and 4. Section 5 investigates consolidated bank-level SB lending in the counties of bank closures. Section 6 discusses impact of the GFC on SB lending community banks and examines robustness of our findings. Section 7 concludes.

2. Data and sample description

To assess how the loss of community banks affects community investment through the impact on small business lending, we compile data from a variety of sources. We collect data on SBL originations by financial

institutions from the Disclosure Reports in the FFIEC’s Community Reinvestment Act (CRA) database that provides detailed data on loan originations by reporting institutions. Specifically, all state member banks, state nonmember banks, national banks, and savings associations with assets more than an annually established threshold (roughly \$1 billion in constant 2005 dollars) for both the prior two calendar years are subject to the data collection and reporting requirements of the CRA. We obtain data on lending from the CRA database for 3,068 unique banks.⁴ We proceed to aggregate SBL originations by reporting CRA banks at the county-year level and use this measure, *SBL originations*, as our main proxy of local community investment. In addition, we use two other proxies for local community investment: *Loans to small firms* and *Total SB loans*. *Loans to small firms* is the aggregate data on loans to firms with less than \$1 million in sales from the FFIEC’s CRA database. *Total SB loans*, incorporates small business lending in a county by non-CRA banks by adding the aggregate Small Business Administration (SBA) 7A loans data for those banks to the *SBL originations* measure at the county-year level.

Next, we obtain data on all bank closures from the Federal Deposit Insurance Corporation’s (FDIC) Research Information System (RIS) merger database and from the FDIC’s Failed Banks list. The merger database identifies all closed institutions and tracks the merger history of all active and inactive FDIC-insured institutions as of a given quarter. The FDIC’s RIS merger database includes the closing date for closing institutions with the following outcomes: merged with assistance; absorption with assistance, or partial purchase and assumption with assistance. We obtain information on failed institutions in which there was no acquirer involved from the FDIC’s list of failed institutions. We identify the closing date, location, and transaction details for all commercial banks (entity type 10) with a closing date between 1999 and 2019. We exclude deals involving banks operating outside of the 50 U.S states or the District of Columbia. Our final sample consists of 5,769 commercial bank closures during our sample period, including 5,640 community banks. We group bank closures into two broad categories: 1) *Merger/consolidation* – for closing institutions with a transaction code of 221 (Absorption), 222 (Consolidated), or 223 (Merger),⁵ and 2) *Failure* – for

⁴ The number of unique banks is based on the FDIC’s certificate number (CERT).

⁵ We use “CODE2XX” from the FDIC’s RIS merger database to classify bank closings by type.

institutions that failed.⁶ In our sample, we have 5,291 (5,164) total (community bank) *Merger/consolidations* and 478 (476) total (community bank) failures. We note that in most bank failures, a new entity takes over primarily in an assisted absorption. Our sample includes only 20 bank failures (out of 478) in which there is no new entity (acquirer) involved.

We proceed to identify the loss of a bank in a county using data from FDIC's Summary of Deposits (SOD) database. Specifically, for our sample of bank closures, we identify all counties in which those banks had a physical presence (defined as a full-service branch) in the last year of their existence.⁷ Next, we construct an indicator variable, *Loss of bank*, which equals one for county c in year t if one or more banks with a presence in year t no longer operate in the county in year $t+1$. For the set of banks leaving a county, we find the reasons for their exit and differentiate between the type of banks that exit a county, focusing primarily on community banks, which could be more important in fostering community development at the local level through small business lending because of their advantages in relationship lending.

We obtain information on county-level measures of employment, population, and additional business conditions from the Bureau of Economic Analysis, the U.S. Census' County Business Patterns (CBP), the U.S. Census Bureau Small Area Income and Poverty Estimates (SAIPE), U.S. Bureau of Labor Statistics (BLS) Local Area Unemployment Statistics, and the Federal Housing Finance Agency. We assess the impact of the loss of community banks in poor and underserved areas by classifying counties as distressed or underserved, following the regulatory agencies' criteria to identify such areas. Specifically, a *Distressed* county is one that meets one or more of the following criteria: 1) unemployment rate > 1.5 times the national unemployment rate; 2) Poverty rate $\geq 20\%$; 3) Population loss greater than or equal to 10% from the previous to the most recent decennial census. Similarly, an *Underserved* county is one with an urban influence code of 7, 10, 11, or 12, as defined by the Economic Research Service of the U.S. Department of Agriculture. Finally, financial data are

⁶ Failures include transaction codes (CODE2XX) of 211 (Absorption- assisted) and 215 (Partial purchase or assumption – assisted), as well as failed banks where there was no acquirer involved, based on the FDIC's Failed Banks list.

⁷ Using the FDIC's SOD database, we focus on banks with branches with code (BRSERTYP) of 11 or 12 [Full service, brick and mortar, and Full service, retail office]. SOD data is collected as of June 30th of each year.

from the quarterly Call Reports from March 1999 through December 2019, obtained from the FDIC's RIS financial time series (FTS) database. Appendix A provides descriptions of variables used in the analyses.

Our final county-level panel dataset consists of 3,151 counties, out of which 91.4% (85.8%) experienced the loss of a bank (community bank). Figure 1 displays the distribution of the sample of community bank closures by year and by type. Most community bank closures (91.6%) during our sample period are a result of mergers/consolidations, which reached a peak of 445 in 2000. Figure 1 shows that the reduction in the number of community banks began well before the GFC and continues throughout our sample period. Community bank failures are rare until the GFC, reaching a peak of 128 in 2010.

Figure 2 is a heat map of community bank closures across counties over the sample period. The figure shows that bank closures are spread out across the country but there are counties that experienced more closures than others, but they are not concentrated in any region of the country. Community development, or activities that revitalize or stabilize distressed or underserved areas, may be affected by the decline in the number of community banks resulting from consolidations that could lead to changes in lending to small and local firms. Thus, later in the paper we assess the implications of bank consolidations on small business lending, with particular focus on the effect in distressed and underserved counties.

Table 1 reports descriptive statistics of the main variables used in our analyses at the county-year level. The table includes our measures of community development and our main measures of community investment, small business lending (SBL) and loans to small firms. The mean total value of *SBL originations* across county-years is \$23.2 million. The mean amount of *Loans to small firms* is \$10.4 million, and that of *Total SB loans*, which includes the aggregate SBA 7A loans by non-CRA banks, is \$24.1 million.⁸

⁸ From Table 1, $\ln(SBL)$ —the natural logarithm of one plus the amount of SBL originations is 10.054. Thus, the average amount of SBL originations is \$23,247,595 $[(\exp^{10.054} - 1) * \$1,000]$. Similarly, the average amount of *Loans to small firms* is \$10,393,166 $[(\exp^{9.249} - 1) * \$1,000]$, and the average amount of *Total SB loans* is \$24,099,792 $[(\exp^{10.090} - 1) * \$1,000]$. We use the natural log of one plus SBL originations because there are zeros in the data for loan originations by size and for loans to small firms.

3. Community investment, community development and the loss of community banks

To examine the importance of local community banks for community investment, we investigate whether community investment is associated with community economic development in section 3.1. Having established a positive impact in section 3.1, we examine whether the loss of community banks in the local market impact community investment in section 3.2.

3.1. Does community investment have an effect on community economic development?

As noted in the introduction, an important belief held by politicians and policy makers is that small businesses are key to economic growth. These firms typically borrow from community banks,⁹ which extant research has shown to have advantages in lending to small businesses through relationship lending (see. e.g., Berger and Udell, 1995, 2002; Berger, et al. 2005; Cole, Goldberg, and White, 2004; Berger, Bouwman and Kim, 2017).¹⁰

In our analysis we use SBL originations as a proxy for direct community investment in small businesses. In Table 2, we examine how the growth in *SBL originations* affects community development using three proxies for community economic development, which include the annual growth in: 1) *Small establishments*—number of firms with fewer than 50 employees; 2) *Employment*—the total employment in the county, and 3) *Small firm employment*—the employment in the county by firms with fewer than 50 employees. Using these measures, we run several specifications of the following model:

$$\Delta Y_{ct} = \alpha + \beta_1 \Delta \ln(SBL)_{c,t-1,t} + Z_{c,t-1} + \gamma_c + \delta_t + \varepsilon_{j,t} \quad (1)$$

$\Delta Y_{c,t}$ refers to our proxies for community development, measured as the change from $t-1$ to t in the natural logarithm of: *Small establishments*, *Employment*, or *Small firm employment*; $\Delta \ln(SBL)_{c,t-1,t}$ is the change in the natural log of $(1 + \text{SBL originations})$ in county c from $t-1$ to t . $Z_{c,t-1}$ is a vector of county-level controls that includes *Population growth*, the annual growth in the county's population; $\ln(wages)$ – natural log of the

⁹ During the 1999 to 2019 period an average of over 53% of community bank loan originations are to small businesses (See Berger and Black (2019) for a review of the literature).

¹⁰ Berger, Goulding, and Rice (2014) argue that improvements in technologies and deregulation in the banking industry may contribute to narrowing the advantages of community banks in using soft information and building relationships with small, opaque firms.

average real wages; *Growth in PCPI*– the growth in per capita income, and *Change in HPI(%)*– annual change in the housing price index. We include county fixed effects (γ_c) to control for time invariant county differences and year fixed effects (δ_t) to control for changes in macroeconomic conditions and technology over time. Standard errors are clustered at the county level.

One concern with using OLS regressions to estimate equation (1) is that omitted factors may affect both SB lending activity and community development. For example, it could be argued that banks increase SB lending activity in counties experiencing higher growth, suggesting a form of reverse causality that complicates the interpretation of our findings as causal. To address these endogeneity concerns, we instrument $\Delta \ln(SBL)$ using a Bartik-like instrumental variable (Bartik, 1991; Blanchard and Katz, 1992; Goldsmith-Pinkham, Sorkin, and Swift, 2020). The approach uses as an instrument for SB loan growth at the county level the (predetermined) share of deposits in each county by community banks and large banks times the aggregate growth in SBL for banks in each size group at the national level. Specifically, our Bartik instrument for $\Delta \ln(SBL)$ is constructed as follows:

$$Bartik_{ct} = \sum_k w_{cs} g_{ts} \quad (2)$$

w_{cs} is county c 's share of deposits held by banks in size group s before the beginning of our sample period (as of 1998);¹¹ s denotes the two bank size groups: *Community* (<\$10B) and *Large* (>\$10B). g_{ts} is computed as the aggregate change in the natural logarithm of SB loans, $\Delta \ln(SBL)$, where SB loans are aggregated across all banks in size group s *outside* the state in which county c is located. We exclude the county's own state in the computation of the aggregate $\Delta \ln(SBL)$ to avoid capturing trends in loan growth that may be correlated with county or state-wide conditions.

We present first- and second-stage results from the estimation of equation (1) using our Bartik instrument in columns (1)-(6) of Table 2. The first- (second-) stage results are shown in the odd- (even-) numbered columns. First-stage results reveal strong explanatory power of our Bartik instrument. The

¹¹ We obtain the share of deposits in each county by banks in each size group from the FDIC's SOD database as of June 1998.

Sanderson-Windmeijer (2016) multivariate F -tests of excluded instruments (F -statistics above 30) easily reject the null of weak instruments.

The second-stage results show that the *Instrumented $\Delta \ln(SBL)$* significantly positively impacts all three proxies for community development. From column (2), a one-standard-deviation increase in the *Instrumented $\Delta \ln(SBL)$* (0.051) is associated with a 0.0069 increase in $\Delta \ln(\text{Small establishments})$ in a county, which represents a 21.6% increase relative to its standard deviation (0.032).¹² We obtain results of similar magnitudes when we use alternate proxies for community development in columns (4) and (6). Overall, the results confirm that small business lending is a positive catalyst for community economic development through its impact on employment growth and growth in small establishments.

3.2. Does the loss of a community bank impact SB lending?

To investigate the effect of a community bank closure on SB lending (our proxy for local community investment), we use a cohort approach and estimate stacked difference-in-differences (DiD) regressions. We use this approach instead of the standard staggered DiD with two-way fixed effects (TWFE), given the issues associated with the interpretability of the TWFE estimator from staggered DiD (Goodman-Bacon, 2019), as well as the inherent bias associated with the staggered DiD estimates (e.g., Barrios (2021), Baker, Larcker, and Wang (2022)). The approach relies on the use of alternative groups to serve as controls (see e.g., Cengiz et al. (2019), Callaway and Sant’Anna (2021), de Chaisemartin and D’Haultfoeuille (2022)). We form treatment cohorts for counties that experience the loss of a community bank in given year, focusing on a narrow seven-year window ($t-3$ to $t+3$) around the *Treatment* (community bank closure) year. We exclude cases in which the treatment counties experience another bank closure within the event window. For each treatment cohort, the control group consists of counties that do not experience the loss of a bank during our sample period (*Never-treated*) and/or those counties that have not yet experienced the loss of a bank (*Not yet treated*). We then evaluate the impact of the loss of a community bank on SBL using the following stacked DiD regression:

$$\ln(SBL)_{c,j,t} = \alpha + \beta_1 Post \times Treat_{c,j} + \beta_2 X_{c,j,t-1} + \gamma_{c,j} + \delta_{t,j} + \varepsilon_{c,j,t} \quad (3)$$

¹² $0.0069 = (0.136 \times 0.051)$, where 0.136 is the coefficient on the *Instrumented $\Delta \ln(SBL)$* in column (2) of Table 3 and 0.051 is its standard deviation. $0.216 = 0.0069/0.032$, where 0.032 is the standard deviation of $\Delta \ln(\text{Small establishments})$.

$\ln(SBL)_{c,j,t}$ refers to the natural log of one plus the amount of *SBL originations (Loans to small firms) {Total SB loans}* in county c and treatment cohort j in year t ; $Post$ is an indicator equal to one starting the year after county c in treatment cohort j loses a community bank and zero otherwise; $Treat$ is an indicator equal to one for the county losing a community bank in cohort j and zero otherwise. $X_{c,j,t-1}$ is a vector of lagged county-level controls that includes *HFI deposits; Loans-to-assets; Capital ratio; NPL-to-loans; % Change in HPI; Population growth; Ln (average wages); Growth in per capita personal income* and *Share of deposits- top 4 banks*. $Treat$ and $Post$ are excluded from the estimation because they are subsumed by the fixed effects, which include county-by-treatment cohort ($\gamma_{c,j}$) and year-by-treatment cohort ($\delta_{t,j}$) to control for time invariant differences between treatment and control counties as well as any secular time trends (Gormley and Matsa (2011)). We cluster standard errors at the county-by-treatment cohort levels.

The results from estimations of equation (3) are shown in Table 3. Overall, the results in Table 3 show that small business lending, $\ln(SBL)$ (*Loans to small firms*) $\{Total SB Loans\}$, is higher in treatment counties in the years after the loss of a community bank relative to the control group. In columns (1)-(3) we use the control group of *Not yet treated* and *Never treated* counties. From column (1), the coefficient on the interaction term, $Post \times Treat$, indicates that $\ln(SBL)$ is 0.071 higher in treatment counties following the loss of a community bank, relative to the control group, which represents a 4.2% increase relative to its standard deviation (1.686). The results are slightly larger in magnitude when we focus on $\ln(Loans\ to\ small\ firms)$ (column (2)). Results are similar when using the broader measure of SB lending activity (*Total SB Loans*) in column (3). In columns (4)-(6) we replicate the results in columns (1)-(3) using an alternate control group, *Never Treated*. The results using the alternate control group are similar in magnitude and statistical significance.

An important assumption in using the stacked DiD analysis is the parallel trends assumption. We estimate equation (3) replacing $Post$ with timing indicator variables equal to one for years $t-3$ through $t+3$ around the community bank closure in the treatment county and include interactions between the timing indicator variables and $Treat$ to test this assumption. Figure 3 graphs the coefficients on the interaction terms, along with 95% confidence intervals. Consistent with the *parallel trends* assumption, the figure shows

insignificant coefficients on the interaction terms between *Treat* and the pre-treatment indicators variables, with positive and significant coefficients on the interaction terms for the post-treatment indicator variables, suggesting that treatment and control counties follow similar patterns in terms of SBL originations in the pre-period, but the difference becomes significant after treatment.

Another possible concern is that bank closures in a county also may affect our control variables leading to the “bad controls” problem in our DiD analysis (See Angrist and Pischke (2009)). To address this potential concern, we replicate the results using controls as of the year before the closure ($t-1$) in each cohort, interacted with the indicator *Post*. Our results, shown in our Internet Appendix confirm our findings.

In additional results, not tabulated for brevity, we examine the impact of FinTech lending in a county and its effect on SB lending by controlling for the fraction of total small business lending in the county by Fintech firms, using data from Gopal and Schnabl(2022).¹³ While the sample is reduced given the data limitations, the results continue to show increases in SBL originations ($Ln(SBL)$ and *Loans to small firms*) after a community bank closure.

As discussed previously, a small set of the bank closures is due to the failure of a community bank. In most of these cases (all except 20 of our community bank failures), a new entity takes over the failed bank. In un-tabulated results, we examine the importance of the difference in the types of closure. The results show that counties experiencing community bank consolidations have a higher increase in $Ln(SBL)$ (*Loans to small firms*) after the loss of a community bank relative to the control group. We observe similar results for counties experiencing community bank failures, although the statistical significance of the results for $Ln(SBL)$ is weaker in those cases. In general, the aggregate results seem counter to conventional beliefs about the importance of the loss of community banks on small business loan originations.

4. Analysis of explanations for the increase in community investment post-community bank closures

The aggregate result that the loss of a community bank is associated with an increase in SB loan originations is puzzling based on prior beliefs related to the impact of community banks on community

¹³ We thank Philipp Schnabl for providing access to his county-level small business FinTech lending data. The data covers the period 2006-2016.

economic development. In this section, we examine potential explanations for this result. One explanation is that community characteristics explain the SB loan originations results since bank success is at least partially affected by the local community attributes. Another potential explanation is that the characteristics of the merged entity affect the community lending after community bank closure. In addition, the results also could be the result of structural changes in SB lending strategy by community banks.

4.1. How do county characteristics matter for understanding the impact of the loss of community banks?

One of the main concerns raised by policy makers about the reduction in the number of community banks is that certain types of counties may be more adversely affected. Our results show that the reduction in community banks lead to an increase in lending, but this could be driven by larger and more developed counties, while counties that are in most need of investment to foster development may experience declines in SB loan originations.

As a first step in exploring the drivers of the rise in SBL originations after community bank closures, we examine the characteristics of counties that are more likely to lose community banks. To do so, we use the panel dataset at the county-year level and estimate linear probability models where the dependent variable is *Loss of a community bank*, an indicator variable equal to one if one or more community banks with physical presence in the county in year t no longer operate in the county in year $t+1$. In addition to the controls used in Table 3 we include *Small establishments %*— the proportion of establishments with fewer than 50 employees, and *Loss of banks >\$10B*, an indicator equal to one if a county experiences the loss of a large bank and zero otherwise.

The results are shown in Table 4. Column (1) shows the baseline specifications. Counties with higher bank deposit concentration, those with a larger share of small establishments, and counties with better capitalized banks are less likely to lose a community bank. In contrast, counties with higher population growth, higher average wages, a larger share of deposits by the big four banks, and with banks with higher non-performing loans have a higher probability of losing a community bank. These results support the idea that there are certain economic county characteristics that are important in predicting the loss of a community bank.

As previously mentioned, the main concerns about disappearing community banks are based on the impact on local development in poorer counties or in those with fewer bank services for small businesses. Importantly, the CRA was created with distressed and underserved counties in mind so that banks would have incentives to invest in such counties to help drive community development. To investigate whether these counties are more likely to lose a community bank, in columns (2) and (3) of Table 4 we add an indicator for *Distressed* and *Underserved* counties, respectively. The results show that *Distressed* counties are less likely to experience the loss of a community bank, while *Underserved* counties are more likely to experience the loss of a community bank. Regulators' focus on distressed counties may explain why such counties are less likely to lose a community bank. Underserved counties are those in more rural areas that tend to have lower bank presence, and results suggest that bank closures are more likely in such counties, where small business creation opportunities may be scarce.

Lastly, we investigate whether the loss of a community bank is, in part, driven by the concentration of community banks in a county. With a high community bank concentration, consolidation could drive to a more efficient distribution of these banks in the county. In column (4) of Table 4 we include *High deposit share-community banks*, an indicator equal to one for counties in which the share of deposits by community banks is in the top tercile of the distribution in a year and zero otherwise. Results show that counties with ex-ante higher share of community banks are more likely to lose a community bank.

Given certain counties are more likely to lose community banks, we examine whether such county attributes impact the effect of community bank closures on community investment. To assess the importance of the loss of a community bank for *Distressed* and *Underserved* counties, we estimate the stacked DiD regressions in equation (3) including interactions with indicator variables for *Distressed* and *Underserved* counties. We show results in Panel A of Table 5. For brevity, we show results using the baseline control group (*Not yet* and *Never treated*). In columns (1)-(3) we show results using interactions with *Distressed*, while columns (4)-(6) show the interactions with *Underserved* counties.

The results in Panel A of Table 5 show that community bank closures do not have differential effects on SB lending in distressed or underserved counties. The coefficients on the triple interaction terms, *Post x Treat x Distressed (Underserved)* are insignificant across all regression specifications. In contrast, the coefficient estimates on *Post x Treat* are positive and statistically significant for *Ln(SBL)* and *Ln (SBL-total)* indicating that overall, the loss of a community bank leads to increases in SB lending activity across all counties.

In Panel B of Table 5, we examine the moderating effect of the concentration of community banks in the county, using interactions with *High deposit share–community banks*. Results in Panel B suggest that the presence of community banks in a county is an important factor contributing to the increase in SBL in counties that experience the loss of a community bank. First, we observe significant positive coefficients on the triple interaction term *Post x Treat x High deposit share–community banks* across all regression specifications. Importantly, the results show that only those counties with a large presence of community banks experience an increase in SB lending after the loss of a community bank. We find no significant effects in other counties (insignificant coefficient on *Post x Treat*). Second, in unreported results we confirm that the increase in *SBL* originations (*Loans to small firms*) is driven by lending by community banks and not large banks. The coefficient on the triple interaction term *Post x Treat x High deposit share–community banks* is positive and significant when using aggregate lending activity by community banks in the county, i.e., *Ln (SBL)-community banks* and *Ln(loans to small firms)-community banks*. In contrast, the coefficient is negative but insignificant in regressions that use lending activity by large banks.

4.2 How do characteristics of the merged bank matter for understanding the effects of the loss of community banks?

As noted, community bank closures are primarily driven by mergers/consolidations and bank failures, to a lesser extent. But even in bank failures, in most cases, a new entity takes over the failed bank primarily through an FDIC-assisted merger; for simplicity, we refer to the new entities as acquirers, even when they take over a failed bank. In this section, we examine the impact of three characteristics related to the new

consolidated entities: the size of the new entity, whether the new entity has a presence in the local county, and the resulting change in SBL lending by its competitors in the county.

In Table 6, we examine whether the consolidated entity's size is associated with the subsequent SB lending activity in that county as strategies related to SBL lending may be correlated with bank size. The analysis thus excludes the 20 community bank closures where there is no acquirer taking over the failed bank. Table 6 shows the results from the estimation of equation (3) that includes interactions with an indicator variable, *Large*, which equals one when the acquirer is a large bank (assets >\$10 billion) and zero otherwise.¹⁴ We use the acquirer size as a proxy for the consolidated entity's size because there are only a few cases in which two community banks merge and increase in size to over \$10 billion in assets. Our results are unchanged if we classify these cases as *Large*. Our sample includes 5,620 community bank closures in which a new entity (acquirer) takes over the closed bank. In 4,845 (775) of those bank closures, the new entity is another community (large) bank. There are only 64 cases in which the new entity is also a community bank, but the consolidated entity's size exceeds \$10 billion (in constant 2019 US\$).

The results in Panel A of Table 6 reveal that the increase in SB lending activity in counties that lose community banks is driven by deals involving a community bank acquirer. The coefficients on the interaction term, *Post x Treat* are positive and statistically significant across all model specifications. In contrast, the results show that the effect is significantly smaller when the acquirer, and hence merged entity, is a large bank as the coefficient estimates on the triple interaction term, *Post x Treat x Large*, are negative and statistically significant. In un-tabulated results, we also examine whether our results are driven by community bank failures or by mergers and consolidations. We find the effect of acquirer size is similar in both types of community bank closures.

The effects of the loss of a community bank in such cases may differ from those cases in which the new consolidated entity continues to have a presence in the county after the community bank closes. We

¹⁴ In cases in which a county has more than one community bank closure in the same year, we code *Large* as one if at least one of those community bank closures involves a large acquirer.

explore this by estimating equation (3) using interactions with an indicator variable, *Presence after*, which equals one if the consolidated entity (acquirer) has a physical presence (a full-service branch) in the closed bank's county after closure, and zero otherwise.¹⁵

We present these results in Panel B of Table 6. Overall, the results show that the increase in *Loans to small firms* is larger after community bank closures in counties in which the new consolidated entity continues to have a presence in the county after the closure, but we find no differential effects on *SBL* and *Total SB loans*. The coefficient estimates on the triple interaction term, *Post x Treat x Presence after* is positive and statistically significant when we use *Loans to small firms* as proxies for community investment. In-county presence of the consolidated entity is thus particularly important when assessing the effects on *Loans to small firms*. As column (2) shows, community bank closures do not lead to increased lending to small firms if the consolidated entity does not remain in the county after the community bank closure (the coefficient on *Post x Treat* is insignificant). In addition, in un-tabulated results, we examine whether the effects of in-county presence differ between closures related to mergers/consolidations and failures. Results show that the positive effects associated with consolidated entity's presence in the closed bank's county is driven by mergers/consolidations, as we find no differential effects in bank failures.

Overall, the results in Table 6 reveal that the size of the acquiring firm, and hence consolidated entity, and whether the consolidated entity maintains a presence in the county after closure is a key factor when assessing the effect of community bank closures on SB lending activity.

We proceed to examine SB lending by other banks in the county by aggregating our proxies for community investment at the county-year level across all banks, excluding lending by the closed entity in the three years before closure as well as any lending by the consolidated entity. We then estimate equation (3) using SB lending by other banks as our dependent variable. That is, we use $\ln(\text{SBL-other banks})$, $\ln(\text{loans to}$

¹⁵ For counties with multiple bank closures in the same year we code *Presence after* as one if at least one of the community bank closures involves an acquirer that retains a physical branch in the county after the closure.

small firms- other banks), and $\ln(\text{Total SB loans- other banks})$ as our explanatory variables. We present the results in Table 7 using the baseline control group (*Not yet* and *Never treated*) for brevity.

The results in Panel A of Table 7 show that other banks in *Treatment* counties increase SB lending activity, relative to the control group, post-community bank closure. The results are both statistically and economically significant. From column (1), results show an increase of 0.092 in $\ln(\text{SBL})$ -*other banks* after the loss of a community bank in the county, relative to the control group, which represents a 5.5% increase relative to its standard deviation (1.68). We observe similar results for our other two proxies for community investment.

Our prior results show that the increase in SB lending following community bank closures in a county is driven by counties with a large presence of community banks. We thus examine whether such an increase is driven by the response of other banks in such counties by including interactions with the indicator *High deposit share-community banks*. The results are reported in Panel B of Table 7 and show a significant increase in lending by other banks post-closure in counties with more ex-ante community bank presence. In other counties, community bank closures have no effect on SB lending activity by other banks (coefficient on *Post x Treat* is insignificant). These results suggest that other local community banks are partially responsible for the observed increase in SB lending activity in counties that lose a community bank. We directly examine this conjecture, by replicating results in Panel B of Table 7, separately assessing the SB lending activity by other community banks and by other large banks in the county. Results confirm that the increase in SB lending activity post-closure in counties with large ex-ante community bank presence is driven by other community banks in the county.

4.3 Did the small business lending strategy change for banks?

So far, the results show that the reduction in the number of community banks is associated with an aggregate increase in SB lending over the sample period. This result could be driven by an evolution of SB lending as there has been changes in technology and SB lending activity over the past two decades. Berger and Black (2011) argue that hard information-based lending technologies allow large banks to expand lending to small firms. Gopal and Schnabl (2022) using unique data on Fintech lending, show that there is an increase in

Fintech lending around the GFC accompanied by increased in SB lending by banks. The results of the study show that Fintech and bank lending increased but maybe in different SB loan types. We examine this idea by focusing on whether the lending strategy of community and large banks changed over the sample period which has implications for the future of SB lending.

The size of community banks has steadily increased partly as a result of consolidation in the industry. As shown in Panel A of Figure 4, the mean and median size of community banks has almost doubled over the sample period. During this period the distribution of loans also evolved differently between large and community banks. Panel B of Figure 4 shows the evolution in SB loan size over the sample period for large banks and community banks. As shown in Panel B there has been a steady increase in small SB loans (less than \$100k) for large banks as a percentage of total SB loans, increasing from 27% in 1999 to 46% in 2019. In contrast, for community banks, as a fraction of total SB loans, small SB loans declined from 26% in 1999 to 17% in 2019.

To better understand the importance of the increased size of community banks and the change in lending by loan size by community and large banks we use the cohort approach and estimate equation (3) using $\ln(SBL)$, $\ln(\text{loans to small firms})$, and $\ln(\text{Loans to large firms})$, aggregated across each type of bank (community and large) as our explanatory variables. We present the results in Table 8 using the baseline control group (*Not yet* and *Never treated*) for brevity. We compute *Loans to large firms* as the difference between *SBL* and *Loans to small firms*. The results are shown in columns (1)-(3) are results for community banks while columns (4)-(6) represent results for large banks. The positive and significant coefficients on *Post x Treat* in columns (1) and (4) show that SBL originations by both large and community banks is higher in *Treatment* counties in the years after the loss of a community bank relative to the control group. Importantly, there is no change in *Loans to small firms* by community banks (Column (2)), while there is a significant increase in loans to small firms by large banks. Conversely, there is a significant increase in *Large SBL* originations by community banks and no change in *Large SBL* originations by large banks in the county post-community bank closure.

One important change during our sample period is the introduction and rapid expansion of Fintech lending to small firms. In un-tabulated results, we control for the concentration of Fintech SB lending in the county. The Fintech data does not cover the full sample period so direct comparisons are not possible. Fintech SB lending presence in the county is positively correlated with lending by large banks who increase lending to small firms after local bank consolidation. Conversely, Fintech concentration is not associated with loans by community banks who tend to provide *Large SBL* originations following local consolidation. This result is consistent with findings of Gopal and Schnabl (2022) who show an increase in Fintech lending along with increases in bank lending following the GFC.¹⁶

5 Bank-County Level Analysis - SB Lending Activity of the Consolidated Entity.

In section 4, we showed that the impact of community bank closures on SB lending varied based on the characteristics of the merged consolidated entity. In this section, we examine more closely the SBL activity at the new consolidated bank level. When a closed bank is taken over by a new entity, the consolidated bank may be financially stronger and able to fund more SB loans, which may partly explain our results. In addition, as shown in Figure 4, the size of community banks has been steadily increasing during the sample period, which indicates that these banks are consolidating perhaps to better meet lending needs in the local community.

In un-tabulated results, we compare the financial performance of a pro-forma bank made up of the closed entity combined with the acquiring entity as of the year prior to the closure. Relative to the pro-forma pre-consolidated bank, we find that the actual consolidated entity in year $t+1$ is more profitable, more stable (lower Z-score), has better asset quality, and is more cost efficient.

To examine whether the new consolidated entity increases SB lending activity post-closure in the closed bank's county, we focus on the SBL activity in the closed bank's main county— the county where the closed bank has the highest concentration of deposits as of $t-1$.¹⁷ From our sample of community bank closures

¹⁶ We thank Philip Schnabl for providing the data on fintech lending at the county level. The data covers the 2006 to 2016 period.

¹⁷ In our sample of 5,620 community bank closures in which a new entity takes over, the closed bank's main county is the county of its headquarters in 91% of the deals. The mean (median) fraction of deposits held by closed banks in their main county is 82.3% (99.8%).

in which a new entity takes over, we form cohorts at the county-closure year consisting of the proforma consolidated entity (treated) and alternate controls groups of other banks with SB lending presence in the treatment county. Specifically, in each cohort, the control group includes banks that did not engage in a consolidation before the closure year (*Not yet treated*) and/or those that did not engage in consolidations during our sample period (*Never Treated*). We construct a pro-forma consolidated entity by aggregating financial data from call reports for the closed bank and the new entity (acquirer). In addition, we aggregate SBL activity at the closed bank-county-year level for the closed bank and the acquirer from $t-3$ to $t-1$ and obtain SBL originations data for the consolidated entity through $t+3$, focusing on the seven-year window ($t-3$ to $t+3$) around each closure in the treatment county. For this analysis we require that the consolidated entity have county-level SBL originations data in both the pre- and post-closure period. We also drop deals in which the treatment counties experience another bank closure within the seven-year window (i.e., we include only non-overlapping deals in a county). Some counties experience several closures in the same year (i.e., some cohorts have multiple treated banks). We collect similar SB lending and financial data for the control group of banks.

We examine SBL activity by the consolidated entity in the closed bank's main county employing the following the following stacked DiD regressions:

$$\ln(SBL)_{icjt} = \alpha + \beta_1 Post_{tj} \times Treat_i + Z_{it} + \gamma_{icj} + \delta_{cjt} \varepsilon_{j,t} \quad (4)$$

where, $\ln(SBL)_{icjt}$ is the natural log of one plus the amount of SBL originations (*Loans to small firms*) for bank i in cohort cj (i.e., in county c and treatment year j) in year t . $Treat_i$ is an indicator that equals one for the proforma consolidated entity(ies) in cohort cj and zero otherwise; $Post_{tj}$ is an indicator variable equal to one starting the year after the bank closure in cohort cj and zero otherwise. Z_{it} is a vector of lagged bank-level controls that includes *Size*- log of book value of assets; *ROA*, net income-to-assets; *Loans-to-assets*; *Capital ratio*, equity-to-assets; *NPL ratio*, nonperforming loans-to-total loans, and *SBL-to-loans*, small business loans-to-total loans. $Treat$ and $Post$ are excluded from the estimation because they are subsumed by the fixed effects, which include bank-by-cohort fixed effects (γ_{icj}) to control for other confounding bank level factors, and

cohort-by-year fixed effects (δ_{cjt}) that control for time-varying county level factors.¹⁸ We double cluster standard errors at the bank and year level.

Results are shown in Table 9. In columns (1)-(2) the control group includes *Not yet* and *Never treated* banks. In columns (3)-(4), we show results using a matched sample in which we match each proforma bank to one of the control banks in the cohort that is closest in size and has similar fraction of SB loans outstanding in its portfolio as of $t-1$.

The results show that the consolidated entity increases lending post-closure in the treatment county relative to the control group. The coefficients on the interaction term $Post \times Treat$ are positive and significant across all model specifications. Taking the coefficient from column (1), results reveal a 0.503 higher increase in $Ln(SBL)$ by the consolidated entity post-closure relative to the control sample, which represents a 7.96% increase relative to its mean (6.32). Results are of similar magnitude for $Ln(Loans\ to\ small\ firms)$ as well as when we use the matched control sample.

We also examine the parallel trends assumption underlying our stacked DiD analysis by replacing $Post$ with timing indicator variables equal to one for years $t-3$ through $t+3$. In line with the parallel-trends assumption, we find insignificant coefficients on the interaction terms between $Treat$ and the pre-treatment indicator variables, with positive and significant coefficients on the interaction terms for the post-treatment indicator variables, which suggests that treatment and control banks follow similar patterns in terms of SBL originations in the pre-closure period. Results are not tabulated.

In Panel B of Table 9, we examine whether the consolidated entity's SBL lending activity differs based on bank size and county characteristics that were shown to affect the county-level results. For brevity, we report results using all control banks, noting that many of the interactions terms are subsumed by the fixed effects. In columns (1)-(4) we show results for $Ln(SBL)$, while columns (5)-(8) show results using $Ln(Loans\ to\ small\ firms)$.

¹⁸ Because our cohorts are formed at the county-bank closure year level, cohort-by-year fixed effects are in essence cohort-by county-year fixed effects that control for time-varying county factors.

Consistent with the county-level results, we find that the post-closure increase in SBL originations by the consolidated entity is smaller when the acquirer is a large bank. While results show no differential effects in distressed and underserved counties, the increase in SB lending is significantly larger in counties with a relatively large presence of other community banks. The latter results suggest that the observed increase in SB lending post-community bank closures is driven by community banks, both incumbent banks as well as by the consolidated entity.

6 The importance of the GFC on SB lending activity and Robustness.

During the sample period the world experienced the GFC, which had very important implications for all banks. Most of the impact was related to increased attention to bank risk taking and closer scrutiny by bank regulators. To examine whether the GFC had an impact on SB lending we re-run our county-level analysis for the pre-GFC period (1999-2006) and the post-GFC period (2010-2020).

In Table 10 we show results from estimations of equation (3) for the pre- (post-) GFC period in the odd- (even-) numbered columns. For brevity, we include results using the baseline control group (*Not yet treated and never treated*). The results show an increase in SBL originations after the loss of a community bank in the post-GFC period, while the coefficient estimates are negative but insignificant on *Post x Treat* in the pre-GFC period.¹⁹ The results suggest that the observed increase in SBL originations in counties that lose a community bank is a post-GFC phenomenon.

In additional analyses, we rerun the analysis of SBL originations by bank size for the pre- and post-GFC period. Results show that in the *pre-GFC* period the loss of a community bank in a county has no effect on subsequent SB lending by community banks. These results suggest that the observed increase in SBL lending after community bank closures is driven by community banks in the post-GFC period. We also replicate results in Table 10 separately for the pre-GFC and post-GFC period for distressed and underserved counties. We do not find a differential effect for distressed counties in either period. For underserved counties, we find negative and significant coefficients on the triple interaction term *Post x Treat x Underserved* in the

¹⁹ This result related to the pre-GFC period is consistent with Jagiani, Korliar, and Maingi (2016) who examine the change in SBL-to-total assets from pre-merger to post-merger relative to peer non-merged banks.

post-GFC period for $\ln(SBL)$ and $\ln(Total\ SB\ loans)$, suggesting that the increase in SB lending following the closure of a community bank is lower in underserved counties in the *post-GFC* period.

While the reactions to the GFC were primarily focused on the risk-taking of large banks, the GFC also had important implications for community banks and their operations as well. Overall, the results suggest that the observed effect on SB lending in the *post-GFC* period is driven by lending activity by community banks. Interestingly, the results also show that the increase in SB lending by other banks after the closure is only significant in the *post-GFC* period. In addition, the increase in SB lending is significantly smaller after bank closures involving large acquirers, but more pronounced in deals in which the merged firm continues to have a presence in the affected county after the bank closure. Though there are potentially clear implications of the GFC for banking in general, there also were many changes related to the growth of banking and data technology along with the expansion of Fintech firms in small business lending. We are unable to disentangle the direct effects of the GFC from these changes but simply use it as a reference point and not necessarily as causal effect.

6.2 Robustness tests.

We conduct a number of robustness tests and present un-tabulated results discussed in previous sections in the internet appendix. In our main analyses, we rely on the event-based stacked regressions approach, using cohorts of treatment counties (counties experiencing a community bank closure) and alternate control groups. To examine the robustness of our results, we replicate our main results but limit our control group to a propensity score (PSM)-matched sample of counties. For each treatment county, we find the closest match based on propensity scores obtained from logit regressions using the indicator *Treat* as a dependent variable. The logit regressions use the same controls used in our main analysis (Table 3). Regressions using the PSM-matched sample continue to show significant increase in SBL originations post-closures in treatment counties, relative to the PSM-matched control county. Using the PSM-matched sample we confirm the results are stronger in the *post-GFC* period and for community bank closures in counties with higher ex-ante community bank presence. The increase in SBL originations is smaller following bank closures involving large bank acquirers.

To further examine the robustness of our results, we estimate panel regressions of SB lending activity in the county using lagged indicators for the loss of a community bank in a county as key explanatory variable. The results confirm that the loss of a community bank is associated with significant increase in SBL originations in the county in the following year. The effect of community bank failures is weaker in these regressions and only significant for loans to small firms.

We also examine the effects associated with the magnitude of the loss of a community bank in a county. Specifically, we estimate regressions using only the treatment group of counties, including interactions between *Post* and *Deposit share-closed bank*- the share of deposits held by the closed bank in the county in the year before its closure. We estimate the regressions using total SBL, and total SBL activity for other banks in the county. The interaction term *Post x Deposit share-closed bank* is positive and significant in regressions using loans to small firms, suggesting that counties in which the closed bank had a larger share of deposits experience a more significant increase in *Loans to small firms* after the bank's closure. When assessing the effect on lending by other banks in the county, we observe positive and significant coefficients across all regression specifications. Thus, counties in which the closed bank held a larger fraction of deposits experience a more significant increase in SBL after the bank's closure.

In addition, to address the “bad controls” problem in our DiD analysis (Angrist and Pischke, 2009), as bank closures in a county may also affect the controls we use, we replicate the results using controls as of the year before the closure (t-1) in each cohort, interacted with the indicator *Post*. We repeat this approach for all results using the DiD analysis and the outcomes confirm our findings. These results are shown in our Internet Appendix.

Finally, we examine the impact of the loss of a community bank using alternate definitions of community banks: 1) Banks with assets <\$2 billion, and 2) Banks designated as community banks, per the FDIC's definition of a community bank²⁰. Results using this alternate definition of a community bank are similar to those presented in the paper.

²⁰ The FDIC's definition of a community bank can be found in Chapter 1 of the FDIC's Community Banking Study: [FDIC Community Banking Study - Chapter 1](#). We obtain the indicator of community banks from the FDIC's RIS database.

7 Conclusion.

There has been a substantial reduction in the number of community banks since the turn of the century. This paper examines how the declining number of community banks affects community economic development. We first show that small business lending positively impacts community economic development. Next, we explore how the closure of community banks affects this development through its impact on small business loan originations in the affected areas.

The impact of community bank closures on community investment is a bit nuanced. Interestingly, we find that in aggregate, community bank closures in a county are associated with a significant subsequent increase in SBL originations in those counties, relative to the control group. The effect is stronger in the post-GFC period. We do not find differential effects in distressed or underserved counties but show that the increase in SBL post-closure is stronger in counties with a high share of deposits by community banks. The increase in SBL is significantly smaller in counties in which consolidated bank is a large bank. In addition, we find stronger effects for loans to small firms for deals in which the consolidated bank retains a presence (i.e., a full-service branch) in the affected county. The positive effects of community bank closures on subsequent SB lending activity in a county is partially driven by the increased SBL lending activity of other local community banks. In additional bank-level results, we find that the consolidated bank increases SB lending in the closed bank's county after closure, relative to the control group of banks. While we focus on community bank closures related to mergers/consolidations and to failures, we find similar effects across both types of closures. Importantly, we find that characteristics of the consolidation matter.

The aggregate finding of an increase in SBL originations in a county following community bank loss is driven primarily by changes in the structure of the small business lending market. We show that community banks have increased in size during the sample period, especially those that consolidate. These large and more stable community banks focus more on larger SB loans and reduced their SB lending to small firms. Conversely, large banks have increased their SB lending to small firms and small SB loans over the same period likely driven by the growth of small loan lending technology. Moreover, the growth of Fintech firms has increased lending for smaller loans and loans to small firms as shown by prior literature.

The paper highlights the importance community banks for community economic development. We observe that only counties experiencing a large presence of community banks benefit when the county experiences a community bank closure. The evidence shows that when a local bank is lost, the characteristics of the new consolidated entity matter. We observe a positive impact on community development when the acquirer is a community bank, but the effect is less pronounced when the acquirer is a large bank. In general, the evidence supports the idea that community bank consolidations often lead to a larger and stronger entity following consolidation that increases community economic development. The evidence also supports an increase in this trend since 2010. Overall, the evidence supports the idea that a one size fits all response to a reduction in the number of community banks is not the right approach to enhance community investment and county level characteristics and consolidated entity decisions should be key considered in any policy response.

Table 1. Descriptive statistics

The table provides descriptive statistics of the main county-level variables used in our analyses. $\Delta \ln(\text{Small establishments})$ is the change in the natural logarithm of establishments with fewer than 50 employees. $\Delta \ln(\text{Employment})$ is the change in the natural logarithm of employment in the county; $\Delta \ln(\text{Small firm employment})$ is the change in the natural logarithm of employment in the county by firms with fewer than 50 employees. $\ln(\text{SBL})$ is the natural logarithm of one plus total small business loan originations by CRA-reporting banks (SBL). $\ln(\text{Loans to small firms})$ is the natural logarithm of one plus loans to firms with revenues less than \$1M. $\ln(\text{Total SB loans})$ is the natural logarithm of one plus the sum of SBL and the aggregate amount of SBA 7A loans by non-CRA reporting banks. Loan amounts are in constant 2019 US \$000s. *Population growth* is the annual growth in a county's population. *Change in HPI* is the growth in the Housing Price index. $\ln(\text{wages})$ is the natural log of the average real wages (wages and salaries divided by total wage and salary employment) in the county. *HFI-deposits* is the Herfindahl index using shares of total deposits by banks in a county. Bank variables (*Loans-to-Assets*, *Capital ratio*, and *NPL-to-Loans*) are weighted averages computed across all banks in the county, using the proportion of banks' local branches as weights. *Shares of deposits of Top 4 banks* is the fraction of total county deposits that are held by the four largest banks in the county. *Distressed county* is an indicator variable equal to one if a county meets at least one of the following criteria: 1) unemployment rate > 1.5 times the national unemployment rate; 2) Poverty rate $\geq 20\%$; 3) Population loss greater than or equal to 10% from the previous decennial census to the most recent decennial census. *Underserved county* is an indicator variable equal to one for counties with an urban influence code of 7, 10, 11, or 12, as defined by the Economic Research Service of the U.S. Department of Agriculture. *Loss of community bank* is an indicator equal to one if one or more community banks with a presence in a county in year t no longer operate in the county in year $t+1$. *Loss of community bank- Closure (Loss of community bank-Exit)* is an indicator equal to one if the loss of a community bank in a county is due to a bank closure (the exit of an active bank from a county). Community banks are those with assets <\$10 billion (constant 2019 US\$). All variables are defined in Appendix A.

<i>Community Development</i>	N	Mean	Median	Std. dev
$\Delta \ln(\text{Small establishments})$	51,574	0.001	0	0.032
$\Delta \ln(\text{Employment})$	51,581	0.005	0.006	0.029

Table 2. Community Investment and Community Development

This table reports the results of 2SLS regressions estimating the determinants of community development. The dependent variables include the change in the natural logarithm of 1) *Small establishments*— number of firms with fewer than 50 employees; 2) *Employment* – the total employment in the county; 3) *Small firm employment*– the employment in the county by firms with fewer than 50 employees. Our key explanatory variable is the $\Delta \ln(SBL)$ — the change in natural log of SBL originations at the county level. Columns (1) through (6) show results from 2SLS regressions in which we instrument *Growth in SBL* with a Bartik-like instrumental variable (Bartik, 1991). Specifically, we use as an instrument for $\Delta \ln(SBL)$ at the county level, the (predetermined) share of deposits in each county by community banks (<\$10B in assets) and large (>\$10B) banks times the aggregate growth in SBL for each type of bank at the national level. The first- (second-) stage results are shown in the even- (odd-) numbered columns. Controls include: *Change in HPI (%)*; *Population growth*; *Ln(wages)*, and *Growth in PCPI*. The last row reports the Sanderson-Windmeijer (2016) multivariate *F*-test of excluded instruments. Standard errors are clustered at the county and year level. *t*-statistics are reported in parentheses. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 3. Loss of community banks and community investment

This table presents results from event-based stacked regressions estimating the effects of the loss of a community bank in a county on small business lending. *SBL* is the amount of small business loan originations; *Loans to small firms* are loans to firms with revenues < \$1 million. *Total SB loans* includes *SBL* (from CRA database) and the aggregate SBA 7A loans in the county for non-CRA reporting banks (those below the CRA-reporting threshold). The dependent variables are the natural log of one plus the amount of *SBL* (*Loans to small firms*) {*Total SB loans*}. The treatment group consists of counties that experience the loss of a community bank. We form cohorts of treatment counties and use as controls counties that have not yet experienced a loss of a community bank or those that did not experience the loss of a community bank during our sample period (Not yet treated and never treated and Never Treated). We restrict the sample period to t-3, to t+3 around the “treatment” year in each cohort. *Post* is an indicator equal to one starting the year after the loss of a community bank in county *c* in a treatment cohort and zero otherwise. *Treat* is an indicator equal to one for counties that lose a community bank and zero otherwise. Controls (unreported to conserve space) include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(average wages)*, *Growth in per capita personal income*, and *Share of deposits- top 4 banks*. We rescale Herfindahl-deposits (dividing it by 1000) in the regressions. We construct the county-level bank characteristics as deposit-weighted averages across all banks in the county using the bank's proportion of local branches as weights. We show results using as controls: Not yet treated and never treated, (columns (1)-(3)) and Never treated (columns (4)-(6)). Standard errors are clustered at the county-by-treatment cohort level. t-statistics are reported in parentheses. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 4. Probability of Losing a Community Bank.

This table reports the results of regressions estimating the probability that a county of loses a community bank. The dependent variable is *Loss of a community bank*, an indicator variable equal one or more community banks with physical presence in the county in year t no longer operate in the county in year $t+1$. *Distressed county* is an indicator variable equal to one if a county meets at least one of the following criteria: 1) unemployment rate > 1.5 times the national unemployment rate; 2) Poverty rate $\geq 20\%$; 3) Population loss greater than or equal to 10% from the previous to the most recent decennial census. *Underserved county* is an indicator variable equal to one for counties with an urban influence code of 7, 10, 11, or 12, as defined by the Economic Research Service of the U.S. Department of Agriculture. *High deposit share-community banks* is an indicator equal to one for counties where the share of deposits held by community banks is in the top tercile of the distribution in a year and zero otherwise. Controls include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(wages)*, *Growth in PCPI*; *Share of deposits- top 4*; *Small establishments %*— the proportion of establishments with fewer than 50 employees. *Loss of banks >\$10B* is an indicator equal to one if a county experiences the loss of a large commercial bank with assets $> \$10$ billion and zero otherwise. We construct the county-level bank characteristics as deposit-weighted averages across all banks in the county using the bank's proportion of local branches as weights. Standard errors are clustered at the county level. t -statistics are reported in parentheses. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 5. Loss of community banks and community investment. By county characteristics.

This table presents results from event-based stacked regressions estimating the effects of the loss of a community bank in a county on small business lending. *SBL* is the amount of small business loan originations; *Loans to small firms* are loans to firms with revenues < \$1 million. *Total SB loans* includes *SBL* (from CRA database) and the aggregate SBA 7A loans in the county for non-CRA reporting banks (those below the CRA-reporting threshold). The dependent variable is the natural logarithm of one plus the amount of *SBL* (*Loans to small firms*) {*Total SB loans*}. The treatment group consists of counties that experience the loss of a community bank. We form cohorts of treatment counties and use as controls counties that have not yet experienced a loss of a community bank and those that did not experience the loss of a community bank during our sample period (*Not yet treated and never treated*). We restrict the sample period to t-3, to t+3 around the “treatment” year in each cohort. *Post* is an indicator equal to one starting the year after the loss of a community bank in county *c* in a treatment cohort and zero otherwise. *Treat* is an indicator equal to one for counties that lose a community bank and zero otherwise. Controls (unreported to conserve space) include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(average wages)*, *Growth in per capita personal income*, and *Share of deposits- top 4 banks*. In Panel A we show results using interactions with two county type indicators: 1) *Distressed county* – an indicator equal to one for counties meeting one of the following criteria: 1) unemployment rate > 1.5 times the national unemployment rate; 2) Poverty rate >=20%; 3) Population loss greater than or equal to 10% from the previous to the most recent decennial census, and 2) *Underserved county* – an indicator equal to one for counties with an urban influence code of 7, 10, 11, or 12, as defined by the Economic Research Service of the U.S. Department of Agriculture. In columns (1)-(3) we show results using *Distressed county* indicator and columns (4)-(6) show results using interactions with *Underserved county*. Standard errors are clustered at the county-by-treatment cohort level. In Panel B we show results using interactions with *High deposit share-community banks* – an indicator equal to one for counties where the share of deposits held by community banks is in the top tercile of the distribution in a year and zero otherwise. *t*-statistics are reported in parentheses. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 6. Loss of community banks and community investment by new entity type.

This table presents results from event-based stacked regressions estimating the effects of the loss of a community bank in a county on small business lending. *SBL* is the amount of small business loan originations; *Loans to small firms* are loans to firms with revenues < \$1 million. *Total SB loans* includes SBL (from CRA database) and the aggregate SBA 7A loans in the county for non-CRA reporting banks (those below the CRA-reporting threshold). The dependent variable is the natural log of one plus the amount of *SBL (Loans to small firms) {Total SB loans}*. The treatment group consists of counties that experience the loss of a community bank. We form cohorts of treatment counties and use as controls counties that have not yet experienced a loss of a community bank and those that did not experience the loss of a community bank during our sample period (*Not yet treated* and *Never treated*). We restrict the sample period to t-3, to t+3 around the “treatment” year in each cohort. *Post* is an indicator equal to one starting the year after the loss of a community bank in county c in a treatment cohort and zero otherwise. *Treat* is an indicator equal to one for counties that lose a community bank and zero otherwise. Controls (unreported to conserve space) include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(average wages)*, *Growth in per capita personal income*, and *Share of deposits- top 4 banks*. In Panel A we show results using interactions with two indicators: 1) *Large* – an indicator equal to one for treatment counties in which the new entity (acquirer) taking over the closed bank is a large bank (>\$10B); and 2) *Presence post-closure* – an indicator equal to one for treatment counties in which the new entity (acquirer) continues to have a presence in the county after the small bank’s closure. In Panel A (B) we show results using interactions with *Large (Presence post closure)*. Standard errors are clustered at the county-by-cohort level. *t*-statistics are reported in parentheses. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 7. Loss of community banks and community investment. Lending by other banks.

This table presents results from event-based stacked regressions estimating the effects of the loss of a community bank in a county on small business lending. *SBL* is the amount of small business loan originations in a county, *excluding* lending by the closed bank and the new entity absorbing the closed bank. *Loans to small firms* are loans to firms with revenues < \$1 million, *excluding* lending by the closed bank and the new entity absorbing the closed bank. *Total SB loans* includes *SBL* (from CRA database) and the aggregate SBA 7A loans in the county for non-CRA reporting banks (those below the CRA-reporting threshold), *excluding* lending by the closed bank and the new entity absorbing the closed bank. The dependent variable is the natural logarithm of one plus the amount of *SBL* (*Loans to small firms*) {*Total SB loans*}. The treatment group consists of counties that experience the loss of a community bank. We form cohorts of treatment counties and use as controls counties that have not yet experienced a loss of a community bank (*Not yet treated*) and those that did not experience the loss of a community bank during our sample period (*Never Treated*). We restrict the sample period to t-3, to t+3 around the “treatment” year in each cohort. *Post* is an indicator equal to one starting the year after the loss of a community bank in county *c* in a treatment cohort and zero otherwise. *Treat* is an indicator equal to one for counties that lose a community bank and zero otherwise. Controls (unreported to conserve space) include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(average wages)*, *Growth in per capita personal income*, and *Share of deposits- top 4 banks*. Panel A shows baseline results. Standard errors are clustered at the county-by-cohort level. In Panel B we show results using interactions with *High deposit share-community banks* – an indicator equal to one for counties where the share of deposits held by community banks is in the top tercile of the distribution in a year and zero otherwise. *t*-statistics are reported in parentheses. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 8. Loss of community banks and community investment. Lending by Community Banks and Large Banks.

This table presents results from event-based stacked regressions estimating the effects of the loss of a community bank in a county on small business lending. *SBL* is the amount of small business loan originations; *Loans to small firms* are loans to firms with revenues < \$1 million. *Loans to large firms* is the difference between *SBL* and Loans to small firms. We aggregate *SBL* (*Loans to small firms*) {*Loans to large firms*} at the county-year level across two types of banks: 1) *Community banks*, and *Large banks*. The dependent variables are the natural log of one plus the amount of *SBL* (*Loans to small firms*) {*Loans to large firms*}. The treatment group consists of counties that experience the loss of a community bank. We form cohorts of treatment counties and use as controls counties that have not yet experienced a loss of a community bank or those that did not experience the loss of a community bank during our sample period (Not yet treated and never treated and Never Treated). We restrict the sample period to t-3, to t+3 around the “treatment” year in each cohort. *Post* is an indicator equal to one starting the year after the loss of a community bank in county c in a treatment cohort and zero otherwise. *Treat* is an indicator equal to one for counties that lose a community bank and zero otherwise. Controls (unreported to conserve space) include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(average wages)*, *Growth in per capita personal income*, and *Share of deposits- top 4 banks*. We rescale Herfindahl-deposits (dividing it by 1000) in the regressions. We construct the county-level bank characteristics as deposit-weighted averages across all banks in the county using the bank's proportion of local branches as weights. We show results using *Not yet treated* and never treated. In columns (1)-(3)) we show results for lending by community banks and columns (4)-(6) show results for lending by large banks. Standard errors are clustered at the county-by-treatment cohort level. t-statistics are reported in parentheses. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 9. Bank-level results. SBL originations around bank closures.

This table presents results from bank-level event-based stacked regressions estimating local small business lending activity by banks around the closure of a community bank in a county. *SBL* is the amount of small business loan originations; *Loans to small firms* are loans to firms with revenues < \$1 million. We form cohorts of treated and control banks at the county-bank closure year. We restrict the sample period to the seven years [-3,+3] around the community bank closure in the closed bank's main county (where the closed bank has the largest presence (share of deposits) as of $t-1$). The control group includes *Not yet treated* banks in the county that did not engage in a consolidation before the treatment year, and banks that did not engage in a consolidation during our sample period (*Never treated*). *Treat* is an indicator equal to one for the proforma consolidated entity (the new entity taking over the closed bank) and zero for the control banks (other banks in the county). *Post* is an indicator variable equal to one starting the year after the bank closure in each cohort and zero otherwise. Bank-level controls include *Size*; *ROA*; *Loans-to-assets*; *Capital ratio*; *NPL ratio*, and *SBL-to-loans*. All regressions include bank-by-cohort fixed effects, and we control for time-varying county level factors by including cohort-by-year fixed effects. In columns (3)-(4) we show results from a matched sample, where we match each treatment bank to a control bank in its cohort that is closest in size and proportion of SB loans outstanding in its loan portfolio. In Panel B, we show results using as controls all other banks in the county including interactions with the following indicator variables: 1) *Large*, which equals one for if the new entity (acquirer) taking over the closed bank is a large bank; 2) *Distressed county*, which equals one for counties meeting one of the following criteria: a) unemployment rate > 1.5 times the national unemployment rate; b) Poverty rate $\geq 20\%$; c) Population loss greater than or equal to 10% from the previous to the most recent decennial census; 3) *Underserved county*, which equals one for counties with an urban influence code of 7, 10, 11, or 12, as defined by the Economic Research Service of the U.S. Department of Agriculture, and 4) *High deposit share-community banks*, which equals one for counties where the share of deposits held by community banks is in the top tercile of the distribution in a year and zero otherwise. All regression include bank-by-cohort fixed effects and cohort-by-year fixed effects. We cluster standard errors at the bank and year level. Robust t -statistics are reported in parentheses. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Table 10. Loss of community banks and community investment, pre- and post-GFC

This table presents results from event-based stacked regressions estimating the effects of the loss of a community bank in a county on small business lending for the pre-GFC (1999-2006) and post-GFC (2010-2019) periods. *SBL* is the amount of small business loan originations; *Loans to small firms* are loans to firms with revenues < \$1 million. *Total SB loans* includes SBL (from CRA database) and the aggregate SBA 7A loans in the county for non-CRA reporting banks (those below the CRA-reporting threshold). The dependent variables are the natural log of one plus the amount of *SBL* (*Loans to small firms*) {*Total SB loans*}. The treatment group consists of counties that experience the loss of a community bank. We form cohorts of treatment counties and use as controls counties that have not yet experienced a loss of a community bank or those that did not experience the loss of a community bank during our sample period (Not yet and never treated and Never Treated). We restrict the sample period to t-3, to t+3 around the “treatment” year in each cohort. *Post* is an indicator equal to one starting the year after the loss of a community bank in county *c* in a treatment cohort and zero otherwise. *Treat* is an indicator equal to one for counties that lose a community bank and zero otherwise. Controls (unreported to conserve space) include: *HFI-deposits*; *Loans-to-assets*; *Capital ratio*; *Nonperforming loans-to-loans*; *Change in HPI (%)*; *Population growth*; *Ln(average wages)*, *Growth in per capita personal income*, and *Share of deposits- top 4 banks*. We rescale Herfindahl-deposits (dividing it by 1000) in the regressions. We construct the county-level bank characteristics as deposit-weighted averages across all banks in the county using the bank's proportion of local branches as weights. We show results using as controls: Not yet treated and Never treated, (columns(1)-(3)) and Not yet treated (columns(4)-(6)). Standard errors are clustered at the county-by-treatment cohort level. t-statistics are reported in parentheses. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A. *** (**) {*} denotes significance at the 1% (5%) {10%} level.

Figure 1. Community Bank Closures.

Figure 1 shows the number and types of community bank closures. Merger/consolidation indicates closing institutions with a transaction code of 221 (Absorption), 222 (Consolidated), or 223 (Merger). Bank failures include those with transaction codes (CODE2XX) of 211 (Absorption- assisted) and 215 (Partial purchase or assumption – assisted), as well as failed banks where there was no acquirer involved, based on the FDIC’s Failed Banks list. Data on closing and failures were obtained from the FDIC’s RIS merger database.

Figure 2. Community Bank Closures by County.

Figure shows the distribution of the number of community bank closures by county from 1999-2019. Community bank closures capture cases involving failure as well as mergers/consolidations of commercial banks with assets <\$10B (in constant 2019 US \$s). Data are obtained from the FDIC's RIS merger database, the FDIC's Bank Failures List, and the SOD database. A county is classified as losing a small bank due to closures if a bank with operations in the county closes during the year.

Figure 3. Diagnostic Test of the Parallel Trends Assumption.

This figure plots the coefficients on the interaction terms between the timing indicators ($t-3, \dots, t+3$) and indicators for our treatment counties (*Treat*) that lose a community bank. The dependent variable is $\ln(\text{SB loans})$, the natural log of one plus SB loan originations (constant 2019 US\$000s) in the county. We form cohorts of treatment counties and use as controls counties that did not experience the loss of a small bank during our sample period (*Never Treated*). We restrict the sample period to $t-3$, to $t+3$ around the “treatment” year in each cohort. Controls are the same ones used in Table 5. The solid dots represent the point estimates, and the lines represent the 95% confidence intervals. *Year 0* is chosen as the benchmark period. Standard errors are clustered at the county-by-treatment cohort level. All regressions include county-by-cohort and year-by-cohort fixed effects. All variables are defined in Appendix A.

Figure 4. Community Bank Size and SB Lending Activity.

Panel A shows the distribution of the size of community banks (in constant 2019 US\$ million) from 1999-2019. Community banks are commercial banks (FDIC's entity type #10) with assets <\$10B (in constant 2019 US \$s). Data are obtained from call reports through the FDIC's RIS database. In Panel B, we show the fraction of total SB loans by loan size for community banks and Large banks. Small SB loans are loans < \$100K; Other SB loans is the sum of medium SB loans (between \$100K and \$250K) and large SB loans (between \$250K and \$1M). Data on SB loans are obtained from the CRA Disclosure files.

Panel A. Community Banks- Size by Year

Panel B. SB Loan Originations by Loan size

Appendix A. Variable Definitions

Variable name	Definition
Capital Ratio	The equity-to-assets ratio. At the county level, we compute the average ratio as the sum of a bank's equity-to-assets ratio multiplied by the bank's proportion of local branches.
Change in HPI (%)	Annual change in the Housing price index from the Federal Housing Finance Agency.
CI loans-to-loans	The ratio of commercial and industrial (C&I) loans-to-total loans. At the county level, we compute the average ratio as the sum of a bank's CI loans-to-loans ratio multiplied by the bank's proportion of local branches.
Community bank	A commercial bank (entity type #10) with total assets less than or equal to \$10 billion (constant 2019 US\$). Source FDIC's RIS FTS database.
Distressed county	A county meeting one of the following criteria: 1) unemployment rate > 1.5 times the national unemployment rate; 2) Poverty rate $\geq 20\%$; 3) Population loss greater than or equal to 10% from the previous to the most recent decennial census.
$\Delta \ln(\text{Employment})$	The change in the natural logarithm of employment in the county. Source: Bureau of Economic Analysis
Failure	An indicator equal to one if the loss of a bank in a county (as defined below) is due to a bank failure. Source: FDIC's RIS merger database.
Growth in PCPI	Growth in per capita personal income in the county. Source: Bureau of Economic Analysis
$\Delta \ln(\text{Small establishments})$	The change in the natural logarithm of the number of establishments with fewer than 50 employees. Source: US Census' County Business Patterns (CBP).
Herfindahl-deposits	Herfindahl index (HFI) using shares of total deposits by banks in a county. $HFI = \sum_{i=1}^N \left[\frac{DEP_{it}}{TOT_{c,t}} \right]^2$ DEP- total deposits by bank i in county c . $TOT_{c,t}$ is the total deposits in county c .
High deposit share-community banks	An indicator equal to one for counties with the share of deposits held by community banks in the top tercile of the distribution in a year and zero otherwise.
Large SBL	Total amount of small business loan originations between \$250K and \$1 million (constant 2019 US\$ 000s). Source: CRA Disclosure files.
$\ln(\text{wages})$	The natural log of the average real wages (wages and salaries divided by total wage and salary employment) in the county. Source: Bureau of Economic Analysis.
Loans-to-assets	The ratio of total loans-to-total assets. At the county level, we compute the average ratio as the sum of a bank's loans-to-assets ratio multiplied by the bank's proportion of local branches.
Loans to small firms	Total amount of small business loan originations to firms with revenues < \$1 million. Source: CRA Disclosure files.
Loss of bank	An indicator equal to one if one or more banks with physical presence in the county in year t no longer operate in the county in year $t+1$.

Appendix A. Variable Definitions. Continued.

Variable name	Definition
Loss of bank- Closure	An indicator equal to one if the loss of a bank in a county (as defined above) is due to bank closures.
Loss of bank- Exit	An indicator equal to one if the loss of a bank in a county (as defined above) is not a result of bank closures.
Medium SBL	Total amount of small business loan originations between \$100K-\$250K (constant 2019 US\$ 000s). Source: CRA Disclosure files.
Merger/consolidation	An indicator equal to one if the loss of a bank in a county (as defined above) is due to bank closures related to an absorption, consolidation, or merger. Source: FDIC's RIS merger database.
NPL ratio	The ratio of nonperforming loans-to-total loans. At the county level, we compute the average ratio as the sum of a bank's NPL-to-loans ratio multiplied by the bank's proportion of local branches, following Berger et al. (2017).
Personal loans-to-loans	The ratio of consumer loans-to-total loans ratio. At the county level, we compute the average ratio as the sum of a bank's consumer loans-to-loans ratio multiplied by the bank's proportion of local branches.
Population growth	The annual growth in the total population in the county. Source: Bureau of Economic Analysis.
RE loans-to-loans	The ratio of total real estate loans-to-total loans. At the county level, we compute the average ratio as the sum of a bank's RE loans-to-loans ratio multiplied by the bank's proportion of local branches.
SBL	Total amount of small business loan originations (constant 2019 US\$ 000s). Source: CRA Disclosure files
SB Loans %	The ratio of SB loans-to-total loans outstanding based on the call report.
Share of deposits- top 4	Share of deposits in the county by the largest four US banks (Citigroup, JP Morgan Chase, Bank of America, and Wells Fargo). Source: FDIC SOD.
Size	The natural log of the book value of assets.
Small SBL	Total amount of small business loan originations <\$100K (constant 2019 US\$ 000s). Source: CRA Disclosure files.
$\Delta \ln$ (Small firm employment)	The change in the natural logarithm of employment by small firms with fewer than 50 employees. Source: US Census' Quarterly Workforce Indicators (QWI) dataset.
Total SB loans	Total amount of small business loan originations (for CRA reporting banks) plus the aggregate amount of SBA 7A loans for non-CRA reporting banks.
Underserved county	A county with an urban influence code of 7, 10, 11, or 12, as defined by the Economic Research Service of the U.S. Department of Agriculture.
