## PREFACE

An important part of the data collected in SIPP is the information in labor force activity. From this data, it is possible to construct work experience data, or "panoramas" of individuals' experiences in the labor market. In this paper, work experience estimates derived from SIPP are compared to those obtained through the March Current Population Survey. In addition, potential uses of SIPP work experience data are discussed as well as the response bias problem found in labor force transition categories.

## INTRODUCTION

Work experience data generally relate to the experiences of individuals in the labor market over a period of time, typically a year. Labor force data, on the other hand, refer to the labor market statuses of individuals--employed, unemployed, not in the labor force--at a point in time, usually a week. The Current Population Survey (CPS), a household survey conducted by the Bureau of the Census for the Bureau of Labor Statistics (BLS), is the chief source of both types of data.

Each month the BLS publishes the labor force data collected in the CPS which relate to the labor force statuses of persons age 16 and over in the previous month (U.S. Bureau of Labor Statistics, 1986). These data receive considerable attention in the media and in policy circles since the Nation's "official" unemployment rate is based on them. Each year the BLS also publishes work experience data, usually for the previous year, which summarize the labor market experiences of individuals during the year (Smith, 1986). These data receive less attention, but nevertheless are used by policy makers and especially labor market researchers.

~~The purpose of this paper is to compare the CPS work experience data with work experience data from the Survey of Income and Program Participation (SIPP) and to discuss various qualitative aspects of the SIPP data.~~ Labor force estimates from both surveys have previously been compared (Ryscavage and Bregger, 1985), consequently this paper is a logical extension of the earlier effort. It is essential to compare these survey results so as to evaluate how well (or poorly) the same phenomena are being measured.

SIPP is a new household survey which began in October 1983. Its objective is to collect information on the economic well-being of persons and households

as reflected in their incomes, assets, and participation in Federal government programs. ~~An important part of the survey is the information obtained on the labor force behavior of persons.~~ Its principal use is as an aid in the interpretation of the income and participation data. Labor market researchers will also be interested in it as another "reading" of labor market behavior.

In this paper, we discuss the similarities and differences of the SIPP and CPS in obtaining work experience data from the population. Then we compare the estimates from both surveys for the 1983-84 period. We go on to show how the SIPP can be used also as a source of data on the length of completed spells of unemployment and their outcomes. A concluding section examines the response error problem detected in the SIPP work experience data and the implications of this for their use.

#### COLLECTING WORK EXPERIENCE DATA

~~The approaches used to collect work experience data in the CPS and SIPP are significantly different.~~ These differences, in many respects, reflect the different goals of each survey--the CPS to collect labor force data and the SIPP to collect income and program participation data. 1/

CPS Questions  
~~The CPS sample consists of approximately 60,000 interviewed households, Each March, as a supplement to the questions asked every month about labor force status, additional questions are asked concerning labor force activity in the previous calendar year. 2/ These questions are straightforward and are designed to find out: 1) if an individual worked, the characteristics of that employment (e.g., full-time, occupation, industry), how long one worked, and for how many employers; 2) if one looked for work or was on layoff, for how long, and how many times and 3) if one was neither working nor looking for work (or layoff), what one was doing. It is important to note that the~~

~~dating of events is not done so it is not known, for example, when a spell of unemployment occurred in the CPS.~~

Together, these questions yield a "panorama" of labor market activity in the previous year for all persons 16 years of age and over. The monthly CPS labor force questions, on the other hand, provide a "snapshot" of labor force activity 12 times a year. Given the dynamic nature of the labor force, that is, the movement of persons in and out of the labor market each month (and the movement of persons between employment and unemployment), the panoramic view identifies a much larger economically active population than the average of the 12 snapshots.

~~The SIPP is significantly different in design from the CPS.~~ It is a longitudinal survey in which sample members are interviewed eight times for roughly a two and one-half year period. <sup>3/</sup> In each wave of interviewing, respondents are asked about their incomes, program participation activity, and labor force statuses in the previous four months-- or reference period (see Figure 1). ~~With respect to labor force statuses, individuals are asked whether they had a job in the reference period and if so in which weeks. Any weeks in which a person did not have a job or was absent from one are identified and a series of questions then seeks to find out if the person had looked for work or the reason for the absence from the job.~~

SIPP is a rotating panel survey, with a new panel beginning each year. The 1984 panel (actually begun in October of 1983) is the focus of this paper and it consisted of approximately 20,000 interviewed households when it began. A panel consists of four rotation groups, one of which is in operation each month, and this results in a staggered sample design (see Figure 1).

Because sample members in SIPP are interviewed over a two and one-half year period, it is possible to develop work experience data not only on a calendar year basis, but for any period of time which does not exceed survey constraints. 4/ In short, SIPP's work experience data are built up from respondents' recollections of weekly labor force statuses in the previous four months, while the CPS data are based on respondents' memories of their labor force activities in a calendar year that took place between 3 to 15 months earlier.

~~Survey methodologists have generally believed that the quality of data collected through a survey with a short recall period would be superior to data obtained with a much longer recall period.~~ It would be logical, therefore, to think that SIPP work experience data would be of a higher quality than that obtained in the CPS. In the next few pages we begin to examine this question.

#### COMPARING SIPP AND CPS WORK EXPERIENCE DATA

Our comparison of SIPP and CPS work experience data must be considered preliminary at this point for a number of reasons. The most important reason is that the SIPP and CPS data we are comparing relate to slightly different time periods. The SIPP estimates span the period from June 1983 to August 1984; this is because of the staggered sample design used in the survey. 5/ Nevertheless, for each rotation group the data relate to a 12 month period. Because the SIPP data bridge 1983 and 1984, it was decided to average the CPS work experience estimates for each calendar year.

Data Results. As the text table below indicates, SIPP showed a greater proportion of the population as being active in the labor market in the 1983-84 period than did the CPS--74.0 percent as compared to 69.5 percent. This would tend to support the notion that because the SIPP interviews occur every four

months as opposed to only once as in the CPS, a more comprehensive accounting of labor force experiences is obtained in the former than the latter.

	<u>SIPP</u>	<u>CPS</u>
Population, age 16 and over (thous.)	<u>175,862</u>	<u>176,771</u>
Total who worked or looked for work or were on layoff (thous.)	130,190	122,810
Percent of population	74.0	69.5
Total who worked during the year/12 month period* (thous.)	122,969	119,362
Percent of population	69.9	67.5
Total who looked for work or were on layoff* (thous.)	30,958	22,649
Percent of population	17.6	12.8

\* Among those who worked during the year are individuals who also looked for work; among those who looked for work are individuals who did not work at all during the period.

The higher labor market activity rate is the result of more persons in SIPP indicating that they looked for work or were on layoff than was the case in the CPS. SIPP found approximately 8.3 million more persons looking for work or on layoff than the CPS. However, SIPP also discovered more persons as having worked--3.6 million more. Tables 1 and 2 take a closer look at these differences.

Table 1a shows the distribution of the weeks worked according to SIPP and CPS in the 1983-84 period. According to SIPP, persons who reported they had a job at some time in this period totaled 123.0 million, compared to 119.4 million in the CPS. This larger "worker count" was accounted for by greater

number of persons reporting they had worked part-time in 1983 and 1984. On the other hand, the SIPP showed about 2.0 million fewer full-time, year round workers than the CPS.

The weeks worked data are further broken down by age and sex in Table 1b and 1c. Among the men, full-time, year-round employment was reported to be quite similar in both surveys--slightly more than 42.5 million. But total part-time employment continued to be larger for the men in SIPP than in the CPS. Among the women, SIPP counted 2.2 million fewer full-time, year-round workers but significantly more part-time workers--close to 4.0 million more. Women in the central ages of 25 to 64 years appeared to be responsible for most of these differences.

Table 2a displays the differences in the SIPP and CPS estimates of looking for work or layoff in the 1983-84 period. The SIPP obtained a much higher estimate of persons looking for work or on layoff--31.0 million vs. 22.6 million. Not only did the SIPP find greater numbers of persons with some work experience in the year who looked for work or were on layoff, but the looking-layoff category was also higher among those with no work experience in 1983-1984. Among workers, looking for work or being on layoff for 1 to 10 weeks was particularly higher in SIPP than in the CPS.

Women accounted for most of the difference in the jobseeking/layoff estimates. According to SIPP, approximately 15.0 million women were looking for work or on layoff compared to 9.6 million as estimated in the CPS. The largest differences were found among teenage women and women age 25 to 64. Again, the estimate of those looking for jobs or on layoff for 1 to 10 weeks a year was much larger in the SIPP than in the CPS. (See Table 2c). Among

the men (Table 2b), the jobseeking/layoff estimates were similar in the 25 to 64 year age group, but quite different among teenage boys and young men.

Speculating About the Differences. In addition to the fact that the work experience data from both surveys relate to different periods of time, many other factors no doubt account for the different work experience estimates from SIPP and CPS. For example, questionnaires differ (as mentioned earlier), the surveys' sample designs differ, the training of interviewers differs, the degree to which information is obtained through telephone interviews differs, and so on.

One very obvious difference alluded to earlier concerns the length of the recall period used in both surveys. SIPP respondents are required to review their labor market experiences over the past four months, whereas in the March CPS respondents must look back over a 12 month period that ended nearly three months prior to the interview. It stands to reason that for even diligent respondents, the task of recollecting is much easier over a shorter period of time than a longer one, especially when the questionnaire for the longer period makes no special effort to help respondents recall the events.

An article by Morgenstern and Barrett (1974) addressed the issue of retrospective bias in unemployment reporting using the labor force data from the monthly CPS and the annual work experience data from the March CPS. They found that ~~unemployment was understated in the work experience data for women and youths. They concluded that this occurred because:~~

~~"...when asked to recollect their unemployment experience (most likely a distasteful task for anyone) of the previous year, these groups, whose part-time employment and movement into and out of the labor force is much greater than average, can and do more easily discount some of their unemployment experience."~~ 6/

The basis for their conclusion was that these groups, while having a higher elasticity of labor force participation with respect to economic activity than middle-age men, may have less anxiety about spells of unemployment since they do not view labor force activity as their primary activity.

While one might quibble with how they perceived the economic roles of women and youth (it was 12 years earlier), there can be no doubt that the strength of labor market attachment will vary in a sample of individuals.

The differences in the SIPP and CPS estimates of looking for work and layoff, of course, were greatest for the women and youth, but it is premature to say that the SIPP data corroborate the Morgenstern and Barrett finding. We need to know more about the SIPP work experience data in general. Moreover, we must explore the differences relating to employment and weeks worked; it could be that the shorter recall period in SIPP is also yielding a more accurate reflection of work activity. Indeed, in the concluding section of this paper possible response biases in the SIPP work experience estimates are discussed.

Potential Application of SIPP Work Experience Data. Because of SIPP's survey design and sequence of labor force questions, the data should be particularly useful in examining topical issues in labor market research. One of these involves estimating completed spells of unemployment and their outcomes. Researchers have delved into this issue using the CPS and other data sources (Clark and Summers, 1979).

The data contained in Table 3 are based on a special SIPP extract file which refers to the September 1983-August 1984 period. 7 The data represent unweighted sample respondents who were neither unemployed in the first or

last week of the period, but who did experience at least one spell of unemployment in the intervening period. One of the problems that has been encountered by researchers in estimating completed spells of unemployment is the censoring or truncation problem, and for this reason we selected the above sample respondents. They totaled 2,866, or approximately one-half of those who were "ever" unemployed in the September 1983-August 1984 period.

For this group of persons the average completed spell of unemployment was 6.4 weeks and approximately 61 percent of the spells ended in employment. But, of course, these broad averages conceal some variation among subgroups, especially with respect to the outcomes of unemployment spells. For men age 25 to 54, 84 percent of their spells resulted in a job, but for teenage women only 44 percent of their spells ended in employment.

~~A very revealing contrast in the outcomes of unemployment spells is seen in the case of whites and blacks: While roughly 66 percent of the spells for whites turned into jobs only 37 percent of the spells for blacks did. Naturally, we would want to know more about the outcome of the unemployment spell than just whether it ended in a job or labor force withdrawal. We might want to know what kind of job was found, how long it lasted, what did it pay, and so forth. Nevertheless, these SIPP data do illustrate their potential for labor market analysis.~~

#### RESPONSE ERROR IN SIPP WORK EXPERIENCE DATA

Problems of between wave response error have been observed in the SIPP program and reciprocity data, specifically with the responses between the last month of one reference period and the first month of the next (Burkehead and Coder, 1985). Similar problems have been found in the labor force data (Ryscavage and Short, 1986). Inconsistent reporting of labor force statuses

between waves of interviewing may affect the estimates of persons working and looking for work or on layoff and bias duration or spell estimates derived from respondents.

To further examine this issue in the context of the SIPP work experience data, we analyzed unweighted data from four waves of interviewing (see Figure 1).

We also utilized the surveys' employment status recodes (ESR's) which summarize a respondent's labor force activities during a month. There are eight

ESR's:

SIPP  
Employment  
Status  
Recode

<u>ESR</u>	<u>Description</u>
1	- With job entire month, worked all weeks.
2	- With job entire month, missed 1 or more weeks, but not because of a layoff.
3	- With job entire month, missed 1 or more weeks because of a layoff.
4	- With job part of month, but not because of a layoff or looking for work.
5	- With job part of month, some time spent on layoff or looking for work.
6	- No job in month, spent entire month on layoff or looking for work.
7	- No job in month, spent part of month on layoff or looking for work.
8	- No job in month, no time spent on layoff or looking for work.

ESR's 3, 4, 5, and 7 contain more than one labor force status in the conventional sense of being employed, unemployed, or not in the labor force because activity is being measured across time and not at a point in time.

ESR's 1, 2, 6, and 8 contain only one labor force status for the month:

1 and 2, employment; 6, unemployment; and 8, not in the labor force.

Average Month-to-Month Transitions in Labor Force Status. As has been reported before, a greater amount of change, or transition, in the ESR's occurs between the reference periods than within the reference periods.

Ryscavage and Short (1986) found that the average month-to-month change in ESR's in the months at the "seams" of the reference periods was 13.1 percent compared to 7.2 percent in months not at the seams of reference periods. In other words, a greater amount of change in labor force status was taking place between two months when the information had been obtained from two interviews rather than just one. Moreover, the transition categories (i.e., the ESR's) responsible for much of the difference were identified.

Table 4 shows which transition categories appear to be accounting for the greatest amount of change in the seam months. It was constructed by subtracting the average of the 12 month-to-month transition matrices in "nonseam" months from the average of the 3 month-to-month transition matrices in "seam" months (see Figure 1). The largest numbers in the table (not including those on the diagonal) indicate where the greatest differences in labor force transitions between seam months and nonseam months were occurring. 8/ Six transition categories stand out:

ESR 1 to 6

ESR 1 to 8

ESR 6 to 1

ESR 6 to 8

ESR 8 to 1

ESR 8 to 6

Note that each of these ESR's contains only one labor force status for the whole month: 1, employed; 6, unemployed; and 8, not in the labor force. Consequently, the transition categories reflect two distinct labor force statuses in two adjacent months.

At this point, we can only suspect a problem exists with these transitions occurring in seam months. Indeed, distinct breaks in labor market activity do occur at month's end (e.g., "I'm through at the end of the month!"). But perhaps we can become legitimately more suspicious if the change in ESR, or labor force status, occurs after four months of the same status followed by four months of another status. For example, an individual may have reported in May that he had a job in the four preceding months, but then in the next interview taking place in September reported that he looked for work the entire subsequent reference period. In other words, his ESR pattern would appear as

ESR's                    1 1 1 1 6 6 6 6

for the first eight months of the year. ~~And in SIPP, there is the possibility for a respondent to report that they were in one particular status for the entire reference period, especially for those who find the survey burdensome or are not concerned with the accuracy of their responses.~~

"Suspicious" Transitions in Labor Force Status. With this possibility in mind, we examined ESR patterns for these suspicious transition categories. The data appear in Table 5. The data show that in the three month-to-month periods which occurred at the seams of reference periods there was an average of 1,930 persons with suspicious ESR changes, the largest groups being ESR's 1 to 8 and 8 to 1. Of the total, 1,287 persons, or 66 percent, had the same ESR for four consecutive months before the seam and a different ESR for four consecutive months after the seam. In ESR categories 6 to 8, 1 to 8, and 8 to 1, the percentages were nearly 70 percent or above. Can we believe that these transitions in labor force status were, in reality, as sharp and as distinct as they were reported? The Table also shows the other ESR wave

patterns among the suspicious transition categories and here too one could question responses.

Obviously, we can only conjecture about the accuracy of the responses from the individuals reporting labor force status changes at the seams and the stability of ESR patterns before and after the seams. For those familiar with the interview process, however, it is very possible that some respondents simply wish to get through the interview so find the easiest path. It is true that it takes much less time to report one status for the entire reference period than to report changes. And the fact that respondents reported a change in status may reflect "telescoping" or simply unconcern with regard to the timing of a labor force status change. 9/ ~~In any event, the pattern of labor force status reporting is summarized by the ESRs makes the accuracy of a significant number of responses questionable.~~

The Affect of Suspicious Transitions on Work Experience Data. In Table 6 we present the age and sex characteristics of persons with suspicious labor force transitions. These data, unlike those just reported, show the number of individuals who had at least one suspicious employment transition, that is, they had one labor force status for four months before the seam and another status for four months after the seam. This Table is more consistent with a work experience concept than Table 5 in the previous discussion which dealt with month-to-month averages.

The Table shows there were 2,923 persons with at least one suspicious transition over the June 1983-December 1984 period. This represents about 12 percent of all the 24,709 sample members that reported some labor market activity in this period. Sample members with a suspicious transition that involved at least one period of looking for work or layoff (the sum of the 1

to 6, 6 to 1, 6 to 8, and 8 to 6 categories) totaled 1,440, or about 24 percent of all persons that reported at least one instance of looking for work or layoff.

Women comprised 57 percent of the total with suspicious transitions, and women in the central ages of 25 to 54 were the single largest age-sex group. When the age-sex categories are examined by specific transition, however, a different picture emerges. In the 1 to 6, 6 to 1 categories, that is, transitions involving employment and unemployment and vice versa, men appeared to predominate. In most of the categories involving transitions between being in the labor force and not being in it (8 to 6, 1 to 8, and 8 to 1) women made up the majority. And, it is these latter categories that make up 66 percent of the total number of suspicious transition categories.

One might speculate that proxy vs. self-reporting of labor force activity could be responsible for the suspicious transitions. That is, a proxy respondent may be more inclined to misreport the labor force status of a sample member either because they are unsure of the individual's labor force status or are simply cavalier in their responses. The data, however, are not convincing on this point. Almost one-half of the suspicious respondents "self-reported" their statuses in both interviews, while only about one-fourth had proxy respondents account for their labor force activity in both interviews.

#### CONCLUSION

The SIPP work experience data offer researchers a new opportunity to examine the dynamic underpinnings of the labor force. Preliminary comparisons indicate that the SIPP data find more people economically active in the labor market than previously reported in the CPS. Considerably more part-time work activity was observed on the part of youth and women. In addition, significant

How do suspicious transitions break down by income, education, occupation?

11 8

cantly more persons reported they had looked for work or were on layoff than was the case in the CPS.

The results of the comparison must be considered preliminary both on the grounds of the nature of the comparison and our investigation into the potential response error in the SIPP data. The comparison of the SIPP and CPS work experience data involved slightly different time periods and a number of survey differences were not controlled for which could also affect the comparisons. Moreover, response error in the SIPP data is evident and must be further investigated. Our exploration of this issue discovered that in a number of instances changes in labor force statuses between interviews are of dubious validity.

- 1/ For information about the CPS see, Technical Paper No. 40, the Current Population Survey: Design and Methodology (1978), and for information concerning, SIPP, see Dawn Nelson, David B. McMillen, and Daniel Kasprzyk, "An Overview of the Survey of Income and Program Participation, Update 1," (1985).
- 2/ See Appendix for facsimilies of the CPS and SIPP questionnaires relating to work experience data.
- 3/ SIPP sample members that move to new addresses are followed and interviewed if possible. In the CPS, sample members are not followed.
- 4/ Work experience data for the 1984 SIPP panel could be developed for the full (all rotation groups) sample for the period beginning in September 1983 and ending in April 1986.
- 5/ The reference period for the first rotation was from June 1983 to May 1984; for the second, from July 1983 to June 1984; for the third, from August 1983, to July 1984, and for the fourth, from September 1983 to August 1984. Because of the staggered sample design, 22 of the 48 rotation group months fall in 1983 and the remaining 26 in 1984. No adjustment was made in the comparison, however, for the slightly greater weight of the 1984 data vis-a-vis the 1983 data.
- 6/ See Morgenstern and Barret (1974), p. 357.
- 7/ This file contained weekly data that enabled the estimation of durations of looking for work and layoff.
- 8/ The diagonal of the transition matrix contains individuals who have not changed their labor force status. Since we have observed a larger amount of change in seam months than in nonseam months (or smaller amount of nonchange in nonseam months than in seam months), when the nonseam matrix is subtracted from the seam matrix, negative numbers result in the diagonal.
- 9/ Mathiowetz (1985) recently reported on the problems of forgetting and telescoping error in unemployment reporting. Based on an analysis of an employer's records and the responses of persons who had been laid off from this employer, she found that over a 30-month reference period, both memory decay and forward and backward telescoping were present in respondents' answers concerning their unemployment experiences. Given the fact that SIPP has a relatively short reference period (relative to the March CPS), it may well be that telescoping is outweighing memory decay.

Table 1a. Extent of employment according to SIPP and CPS -- 1983-84 1/

Section 1 - LABOR FORCE AND RECIPIENCY

(SHOW FLASHCARD J)

**1.** During the 4-month period outlined on this calendar, that is, from (4 months ago) thru (Last month), did ... have a job or business, either full time or part time, even for only a few days?  
 Mark "Yes" for active duty in the Armed Forces, any temporary or part-time work, and work without pay in a family business or farm.

1000  Yes - Mark "Worked" (code 170) on ISS and SKIP to 4  
 No

**2a.** Even though ... did not have a job during this period, did ... spend any time looking for work or on layoff from a job?

1002  Yes  
 No - SKIP to 3a

**b.** Please look at the calendar. In which weeks was ... looking for work or on layoff from a job?  
 Mark (X) all that apply.

1004	<input type="checkbox"/> ALL				
1006	<input type="checkbox"/> 1	1018	<input type="checkbox"/> 7	1030	<input type="checkbox"/> 13
1008	<input type="checkbox"/> 2	1020	<input type="checkbox"/> 8	1032	<input type="checkbox"/> 14
1010	<input type="checkbox"/> 3	1022	<input type="checkbox"/> 9	1034	<input type="checkbox"/> 15
1012	<input type="checkbox"/> 4	1024	<input type="checkbox"/> 10	1036	<input type="checkbox"/> 16
1014	<input type="checkbox"/> 5	1026	<input type="checkbox"/> 11	1038	<input type="checkbox"/> 17
1016	<input type="checkbox"/> 6	1028	<input type="checkbox"/> 12	1040	<input type="checkbox"/> 18

**c.** Could ... have taken a job during any of these weeks if one had been offered?

1042  Yes - SKIP to Check Item A1  
 No

**d.** What was the main reason ... could not take a job during these weeks?  
 Mark (X) only one.

1044  Already had a job  
 Temporary illness  
 School  
 Other - Specify \_\_\_\_\_

**CHECK ITEM R1** Refer to item 2b. Is the "ALL" box marked in 2b?

1046  Yes - SKIP to 9a, page 4  
 No - SKIP to 3b

**3a.** Were there any weeks in the 4-month period when ... wanted a job?

1048  Yes - SKIP to 3c  
 No - SKIP to Check Item A6, page 4

**b.** I have recorded that there were weeks that ... did not work or look for work. Did ... want a job in these weeks?

1050  Yes  
 No - SKIP to 9a, page 4

**c.** Could ... have taken a job in those weeks if one had been offered?

1052  Yes  
 No - SKIP to 9a, page 4

**d.** During the weeks that ... wanted a job but was not looking for one, what was the main reason ... was not looking?  
 Mark (X) only one.

1054  Believes no work available in line of work or area  
 Couldn't find any work  
 Lacks necessary schooling, training, skills, or experience  
 Employers think too young or too old  
 Other personal handicap in finding job  
 Can't arrange child care  
 Family responsibilities  
 In school or other training  
 Ill health, physical disability  
 Other - Specify \_\_\_\_\_  
 DK

SKIP to 9a, page 4

**4.** Did ... have a job or business, either full or part time, during EACH of the weeks in this period?  
 Note that the person did not have to work each week.

1058  Yes  
 No - SKIP to 6a

**5a.** Was ... absent without pay from ...'s job or business for any FULL weeks during the 4-month period?

1059  Yes  
 No - SKIP to 8a, page 4

**b.** Please look at the calendar. In which weeks was ... absent without pay?  
 Mark (X) all that apply.

1060	<input type="checkbox"/> ALL				
1062	<input type="checkbox"/> 1	1074	<input type="checkbox"/> 7	1086	<input type="checkbox"/> 13
