#### Abstract

Between 1898 and 1948, English was the language of instruction for most postprimary grades in Puerto Rican public schools. Since 1949, the language of instruction in all grades has been Spanish. We use this policy change to estimate the effect of English-intensive instruction on the English-language skills of Puerto Ricans. Although naïve estimates suggest that English instruction increased English-speaking ability among Puerto Rican natives, estimates that allow for education-specific cohort trends show no effect. This result is surprising in light of the strong presumption by American policymakers at the time that English instruction was the best way to raise English proficiency. It suggests that increased emphasis on using English as the language of instruction may do little to benefit Puerto Ricans who remain on the island today. (JEL I28, J15, J24)

[^0]On the morning of January 2, 1949, the first elected governor of Puerto Rico took office. In the afternoon, he appointed Mariano Villaronga as the Commissioner of Education. Villaronga had been appointed to the same post by President Truman in December 1946, but resigned in June 1947 because the U.S. Senate refused to confirm his appointment. The Senate had stalled Villaronga's confirmation indefinitely because he had said that if confirmed, he would make Spanish the primary medium of instruction in Puerto Rican schools. Philleo Nash, an advisor to President Truman on issues related to U.S. territories, recalled that "all previous incumbents [in the Commissioner of Education post] had had a condition set on them that they would have English be the language in the schools, or they wouldn't get confirmed by the United States Senate. The Senate was standing firm, at least the Senate committee [on Territories and Insular Possessions] was, and was refusing to approve Villaronga" (Hess 1966, p. 320). Upon returning as Commissioner of Education in 1949, Villaronga made Spanish the language of instruction in all grades in public schools, with English taught as a subject. The Villaronga policy remains in effect today.

Although Puerto Rico's language shift is over a half-century old, the extent and timing of English-only instruction for non-native English speakers remains one of the most controversial aspects of U.S. education policy. Recent years have seen a move away from bilingual instruction for non-native English speakers towards English-only instruction and a "sink or swim" approach (Zehler et al. 2003). Typical of this shift is the effort to impose English-only instruction through state ballot initiatives, which have been approved in California (1998), Arizona (2000), and Massachusetts (2002). ${ }^{1}$ Federal legislation has also moved to favor English-only instruction: in 2002, the Bilingual Education Act was replaced by the English Language Acquisition Act (Title

[^1]III of the No Child Left Behind Act). As a result, federal aid for limited-English-proficient students changed from a competitive grant system favoring native-language instruction to a formula grant system based on the number of limited-English-proficient students and immigrant students in each state. The new accountability requirements accompanying formula-based grants discourage schools from using native-language instruction (Crawford 2003).

In this paper, we use Puerto Rico's 1949 reform to gauge the importance of Englishintensive instruction for Puerto Ricans' ability to speak English. The 1949 language reform required universal Spanish-only instruction after a half century of instruction in English in postprimary grades. To identify the effect of the switch to Spanish, we take advantage of two sources of variation. On one hand, among individuals growing up in Puerto Rico, cohorts educated in the post-reform period were schooled in Spanish. At the same time, the reform changed the language of instruction only for those completing five or more years of schooling because lower grades were taught in Spanish even before the 1949 reform. The extent of an individual's exposure to English-intensive instruction was therefore determined by interactions between his year of birth and years of schooling. Use of these interactions to capture language policy effects leads to a difference-in-differences-type identification strategy across cohort and schooling groups.

To validate this strategy and provide an additional source of control for omitted variables, we use comparison groups that never experienced a change in language of instruction, such as earlier and later cohorts of Puerto Ricans and immigrants from former Spanish colonies. Our statistical analysis exploits the fact that the U.S. Census covers Puerto Rico as well as the U.S. mainland. Thus, we can analyze samples of island-born individuals regardless of where they choose to live. In particular, we use data from the 1980 and 1990 U.S. Census of Population and

Housing Public Use Microdata Samples (PUMS) for Puerto Rico and the mainland.
As far as we know, ours is the first rigorous evaluation of the 1949 language reform. ${ }^{2}$ An assessment of the consequences of this reform should be of interest for at least two reasons. First, some observers see the 1949 reform as contributing to relatively low levels of English proficiency among Puerto Ricans today, and favor bringing back English-language instruction in some grades and subjects in order to raise English proficiency. Time-series data on the English proficiency of the Puerto Rican-born provide some support for the view. Figure 1, which plots cohort trends in English proficiency as observed in the 1980 and 1990 PUMS, shows a continuous increase in English proficiency that flattens after the last cohort (born 1933) to receive English-intensive instruction. Among cohorts born 1934 and later, there is a persistent "language gap," in that one-third of these cohorts speak no English. Since the language gap stopped narrowing after Spanish-only schooling was introduced, it is natural to ask whether the school policies regarding language of instruction explain this.

In addition to the implications of language reform for Puerto Ricans themselves, the Puerto Rican experience should also be of more general interest. Over eight percent of students enrolled in U.S. public schools are classified as limited-English-proficient (LEP), of whom threequarters are Hispanic. ${ }^{3}$ From 1980 to 1999, enrollment of LEP students doubled but total enrollment grew by only $25 \%$. The question of how to teach children with limited English proficiency remains controversial. Although a large literature attempts to evaluate programs for such children, few of these studies have convincing research designs. In particular, few studies

[^2]address the endogeneity of program participation or other sources of omitted variables bias. ${ }^{4}$ The variation in exposure to English-intensive instruction used in this paper arises from a sharp policy change, the consequences of which should be relatively easy to assess.

The paper is organized as follows. Section I provides some background on the 1949 language reform and outlines our main identification strategy. Section II describes the data sources and presents some descriptive statistics. Section III discusses the empirical results. Section IV presents estimates of the effects of English-intensive instruction using an alternative identification strategy that relies on comparisons with immigrants. The paper concludes in Section $V$ with a discussion of possible explanations for the findings.

## I. Background and Identification Strategy

## A. Background

After four hundred years as a Spanish colony, Puerto Rico became an American possession in 1898 as a result of the Treaty of Paris which ended the Spanish-American War. The U.S. took an active role in the island's administration, particularly in education. ${ }^{5}$ One American goal was to expand the public school system. Under Spanish rule, educational opportunities had, for the most part, been reserved for the elite. A second goal was to teach Puerto Ricans English as part of a process of Americanization.

The American administration set up a U.S.-style school system providing free education

[^3]through $12^{\text {th }}$ grade. ${ }^{6}$ Schooling was compulsory for those aged $8-14$, though in practice the compulsory schooling law was of little consequence since many rural communities had no school offering grades beyond $4^{\text {th }}$. To increase access, the number of public school teachers was increased from 897 in 1900 to 9101 in 1948 (Osuna 1949, p. 607, Table II). Nominal spending on public education increased from half a million dollars to $\$ 21.4$ million over the same period (Osuna 1949, p. 607, Table II). Figure 2 documents the rise in public school enrollment in Puerto Rico among children aged 6 to 18 . In 1900, only $8 \%$ of the population aged 6 to 18 (i.e., 26,204 children) was in school; enrollment rates in public schools exceeded 50 percent by the time of the 1949 language reform and continued to climb thereafter, peaking at almost 80 percent in $1980{ }^{7}$

The growth in enrollment generated dramatic increases in educational attainment. Individuals born 1914-23 had an average of 6.4 years of schooling, but those born 10, 20 and 30 years later had 7.9, 9.3 and 10.7 years of schooling, respectively. Much of the increase in attainment came from a shift in the distribution of years of schooling from four or fewer to more than four years. This can be seen in Figure 3, which plots the cumulative distribution of educational attainment for the Puerto Rican-born population by cohort. Forty-two percent of those born 1914-23 had zero to four years of schooling, compared with $29 \%$ of those born 1924-
$33,16 \%$ of those born 1934-43, and 8\% of those born 1944-53.
The effort to increase English proficiency proved to be at least as much of a challenge as

[^4]increasing access to public education. One difficulty was the lack of consensus over the appropriate pedagogical method for achieving this goal. Some educators favored the use of English as the only language of instruction in all grades, but others favored Spanish in the early grades and English in later grades. Between 1898 and 1948, language policy changed several times, reflecting the views of different Commissioners of Education. These shifts are summarized in Table 1, which shows that a common feature of public education during this period was English-language instruction in at least some grades.

A second difficulty was a shortage of teachers who knew English. As a result, teachers were recruited from the mainland and in-service training courses were used to prepare island teachers to teach in English (Osuna 1949, Chapter IX). Also, the University of Puerto Rico was established in 1903 to generate a supply of new island-born teachers who could teach in English. These strategies increased the number of English-proficient teachers so that compliance with English-only instruction policies became feasible.

Given the logistical effort and additional personnel required to expand instruction in English, it is worth documenting the success of this effort and the extent to which the 1949 language-policy reversal was meaningful. Describing high schools around 1920, Osuna (1949) observes: "With the exception of Spanish, which was taught as a subject, the official language of the high school was English" (p. 248). Similarly, the Report of the Commissioner of Education for the 1947-48 school year states that English "is the medium of instruction in the senior high school in all classes except the Spanish class and the class in Puerto Rican history" (p. 25). The report for the 1948-49 school year, halfway through which Villaronga began serving as the Commissioner of Education, mentions plans for "the introduction of Spanish as the medium of instruction...in the senior high schools in the following year" (p.24).

As the supply of teachers capable of teaching in English increased and with the elimination of English-only instruction in grades 1-4 in 1916, it also became increasingly practicable to comply with the language of instruction policies listed in Table 1 even in grades below the high school level. By the 1911-12 school year, $98 \%$ of 771 urban elementary schools and $17 \%$ of 1097 rural elementary schools used only English (Osuna, 1949, p. 346). ${ }^{8}$ Even if rural areas had ignored English-only instruction, the proportion of pupils schooled in English would have been high since most of the post-primary enrollment was in urban areas. For example, in $1940,57 \%$ of $5^{\text {th }}$ graders, $77 \%$ of $8^{\text {th }}$ graders and $100 \%$ of $10^{\text {th }}$ graders were attending schools in urban areas. ${ }^{9}$

## B. Identification Strategy

The effect of English-intensive instruction on English proficiency is identified here using a difference-in-differences-type strategy that exploits variation in exposure to English-intensive instruction across cohorts and schooling levels. This variation is documented in Table 2, which

[^5]shows potential years of exposure to English-intensive schooling by year of birth and years of completed schooling. Thus, variation in exposure arises from differences in the timing and amount of school attendance. It is worth emphasizing that Table 2 reflects potential exposure since some children start school at different ages, repeat grades, or withdraw temporarily. The results discussed below are unchanged when the exposure variable is coded allowing for modest levels of delayed school entry and grade repetition.

The identification strategy we use resembles the one used by Angrist and Lavy (1997) to estimate the effects of a change in language of instruction from French to Arabic in Morocco. The empirical analysis below allows the effect of English-intensive instruction to vary by years of potential exposure to English-intensive instruction. Among the cohorts studied here (born 1914-63), treatment intensity varied from $0-8$ years. We report estimates of the coefficients on eight treatment dummies, denoted $\beta_{\mathrm{m}} ; m=1, \ldots, 8$; in the following equation:
(1) $y_{i j k}=\alpha+\sum_{m=1}^{8} \beta_{m} I\left(E_{j k}=m\right)+\theta_{j}+\rho_{k}+\varepsilon_{i j k}$
for individual $i$ born in year $j$ with $k$ years of schooling where $\mathrm{I}(\cdot)$ is the indicator function. The dependent variable, $\mathrm{y}_{i j k}$, is a measure of English proficiency and $E_{j k}$ is years of potential exposure to English-intensive instruction. The parameter $\theta_{j}$ is a cohort effect, controlling for cohort trends common to schooling groups, while $\rho_{k}$ is an educational attainment-specific effect, controlling for the fact that less-educated people probably have weaker English skills.

The interpretation of $\beta_{\mathrm{m}}$ as the causal effect of receiving $m$ years of English-intensive instruction rests on the assumption that the coefficients for interactions between birth cohort and years of schooling would be zero without the 1949 language reform. However, the cohort trend in English proficiency may differ across schooling groups for various reasons. The empirical
analysis therefore uses various groups of non-exposed controls to test and modify the basic identification strategy. We also estimate specifications that explicitly allow for differential cohort-specific trends across schooling groups.

## II. Data and Descriptive Statistics

The empirical analysis pools individual-level data from the U.S. Census of Population and Housing for 1980 and 1990 for Puerto Rico and the mainland. ${ }^{10}$ Similar questionnaires have been fielded in both places so we can assemble a data set of consistently-defined variables for Puerto Ricans regardless of whether they live on the island or the mainland. Most importantly, self-reported information on English-speaking ability has been solicited on Puerto Rico's census form for decades and was added to the mainland census form in 1980. Although the language question is asked differently on the two forms, we are able to construct a uniform set of dummy variables indicating English-speaking proficiency. ${ }^{11}$

A natural concern is the extent to which self-reported English-speaking ability is a meaningful measure of English-language skills. The Census language question has been validated in two ways, both described by Kominski (1989). First, the English Language Proficiency Study, conducted in 1982 by the Census Bureau for the Department of Education, incorporated standardized tests of English-language skills. The results on this test were shown to

[^6]be highly correlated with Census self-reported English-speaking ability; for example, those responding "speaks English very well" in the census questionnaire had standardized test scores similar to a native English-speaking control population, while score levels fell markedly when self-reported English-speaking ability was lower. A second validation effort compared Census self-reported English-speaking ability with other measures of English-language skills taken from the National Content Test administered by the Census Bureau in 1986. These results showed Census self-reports to be highly correlated with functional measures of language skills such as English reading and writing skills and whether respondents used English at work.

Most of our analysis uses samples of people born in Puerto Rico. Since passage of the Jones Act in 1917, which granted U.S. citizenship to all Puerto Ricans, islanders have been able to travel freely and settle anywhere in the U.S. mainland and possessions. Significant migration to the mainland began in the 1950s, and by 1970 approximately one-third of those born in Puerto Rico lived on the mainland. Because virtually all Puerto Ricans live either in Puerto Rico or on the mainland, the combination of mainland and Puerto Rican census data provides a representative sample of all people born in Puerto Rico. This allows us to sidestep the problem of selective migration when examining the impact of the language reform.

Our main analysis uses cohorts born 1924-43. ${ }^{12}$ This yields a narrow window that contains sufficiently many observations; a longer window would likely make the need to control for education-specific cohort trends even more acute. We think of those born 1924-33 as the treatment cohorts (i.e., exposed to English-intensive instruction) since they would have been schooled in the pre-reform period with at least one year of English-intensive instruction. The 1933 cohort caught the tail end of English-intensive instruction, exposed for one-third of a year

[^7]in $3^{\text {rd }}$ grade, 3 years in junior high school, and one year in high school (since this cohort was in $10^{\text {th }}$ grade in 1948). The control cohorts begin with those born in 1934 because this cohort entered first grade in 1940, just missing English-intensive instruction in primary grades as required by the Gallardo policy. Moreover, the 1934 cohort entered junior high school (grades 7-9) in 1946, when the officially condoned though still unofficial policy was to phase out English. Finally, this cohort would have entered senior high school (grades 10-12) in 1949, when the 1949 language reform eliminating instruction in English took effect.

Appendix Table 1 shows descriptive statistics for the treatment cohorts and control cohorts born 10 years later than the treatment cohorts, as well as for three additional cohorts (born 10 years earlier, and 20 and 30 years later than the treatment cohorts) used for specification testing. For the treated cohort, the average potential years of exposure to English-intensive instruction was 2.85 years. Those completing five or more years of schooling had on average four potential years of English-intensive instruction and those completing four or fewer years of schooling had none.

## III. Results

## A. Difference-in-Differences Estimates

Table 3 reports ordinary least squares estimates of equation (1) using the sample born 1924-43. ${ }^{13}$ Although only the coefficients for the treatment dummies are reported, the regressions used to construct these estimates also control for a full set of schooling, year of birth, age and sex dummies, as well as for potential experience and year of observation. The results indicate that those who received English-intensive instruction were significantly more likely to speak English. For example, the effect of receiving six years of English-intensive instruction on

[^8]the probability of speaking English is $3.54 \%$ (column 1). Those receiving more than one year of treatment are more likely to speak English than those receiving only one year, however, the treatment effects do not increase monotonically with years of treatment. Column 2 shows that those who received English-intensive instruction are also significantly more likely to speak English well. The estimates in this case increase with years of exposure, consistent with the notion that stronger English-language skills take time to develop.

Control for mainland residence has little effect on the results. This can be seen in columns 3 and 4, which report results from models that include a dummy for mainland residence. The robustness to inclusion of the control for residence is encouraging since, although residence is potentially endogenous (with language skills affecting the decision to migrate), the fact that the island and mainland language questions differ is a potential concern in pooled samples. We would therefore like to look at estimates for island residents only. As it turns out, estimates using Puerto Rico residents only, reported in columns 5 and 6, resemble the estimates generated using the sample of all Puerto Rican-born.

## B. Controlling for Differential Trends

The estimates in Table 3, which point to better English-language skills for those instructed in English, may be confounded with education-specific cohort trends in English proficiency. Such trends could have arisen through several channels, primarily as a by-product of the rapid expansion of the Puerto Rican public education system for affected cohorts. First, as access to education spread, the average ability of more educated people may have fallen. Second, rapid expansion of the public school system may have led to a decline in the quality of upper-grade classrooms relative to lower-grade classrooms. Third, because the dependent
variable in Table 3 is binary, an additive linear probability model may induce spurious cohortschooling trends. Fourth, although most schools with more than the first four grades were located in cities and towns, access to upper grades was becoming increasingly common in rural areas. Finally, some Puerto Ricans may have developed English-language skills when they served in the U.S. military, and service was more prevalent among older and more educated cohorts. All of these channels may generate spurious treatment effects, since the treated group consists of relatively old and more-educated cohorts. We examine these sources of bias in subsection IIIC; here, we focus on testing for the presence of differential trends.

A natural comparison group for the investigation of confounding education-cohort trends can be drawn from the populations both older and younger than the two 10-year cohorts analyzed in Table 3. Schooling was increasing similarly for these cohorts, a fact documented in Figure 3. The figure shows marked shifts in the schooling distribution as we move from one 10 -year cohort to another. English proficiency levels in cohorts other than the treated cohort may therefore reflect some of the same schooling-specific trends.

As a first pass at a formal falsification test, we repeated a Table 3-type analysis using pairs of 10-year birth cohorts unaffected by the reform. These results are shown in Table 4. For comparison, results using the original treatment and control cohorts are reported in columns 1 and 2. Columns 3 and 4 show results for two cohorts that we think of as always treated (i.e, both were born 1933 or earlier), while columns 5 and 6 use two cohorts that were never treated (i.e., both were born 1934 or later). Finally, columns 7 and 8 show results for a second pair of nevertreated cohorts, born 1944-53 and 1954-63.

For the purposes of this specification check, we assigned a pseudo-treatment variable as if the older cohort in each pairing had been born 1924-33, i.e., using the assignment rule for the
original treatment and control cohorts. For example, to produce the estimates in column 3 and 4, we assume that those born 1914-23 were treated as if they had been born 1924-33 and those born 1924-33 were never treated. This falsification test generates spurious treatment effects. The hypothesis that the eight pseudo-treatment effects are jointly zero can be rejected at the $99 \%$ level in each column. Moreover, the magnitudes of the coefficients in the falsification experiments are similar to the magnitudes in columns 1 and 2, for the affected cohorts.

While Table 4 generates clear evidence of confounding trends, it remains possible that the treatment-control contrast for the cohorts actually experiencing a change in language policy still exceeds that for the falsification cohorts, perhaps significantly. As a check on this, we employed a triple differences regression strategy which uses the falsification cohorts to net out the cohort-education trend associated with treatment status. In particular, we estimated the following equation using the cohorts born 1924-63:
(2) $y_{i j k}=\alpha+\sum_{m=1}^{8} \beta_{m} I\left(E_{j k}=m\right)+\sum_{m=1}^{8} \delta_{m} I\left(E T_{j k}=m\right)+\theta_{j}+\rho_{k}+\pi_{k} I(j \geq 1944)+\varepsilon_{i j k}$
for individual $i$ born in year $j$ with $k$ years of schooling, and where $E T_{j k}$ is the exposure trend. For those born 1924-43, $E T_{j k}$ equals $E_{j k}$, and for those born 1944-63, $E T_{j k}$ equals years of pseudotreatment, i.e., treatment status assigned as if these cohorts had been born 20 years earlier. The resulting estimates of $\beta_{\mathrm{m}}$ equal the treatment effects from Table 3 minus the pseudo-treatment effects (differential trends) estimated using the younger cohorts born 1944-63. The results, reported in Table 5, show that controlling for differential trends eliminates any positive effects of English-intensive instruction on English proficiency.

## C. Sources of Differential Trends <br> 1. Decreasing selectivity in higher grades

What might account for the cohort-schooling trends that appear to be confounding the estimates in Table 3? One possible explanation is that positive selection into higher levels of education was stronger in the past. As education spread and compulsory schooling laws were increasingly enforced, those with less ability or from a more disadvantaged family background increasingly entered higher grades. As a result, the well-educated from more recent cohorts might have been less likely to speak English than the well-educated from earlier cohorts.

To check on this version of the selection hypothesis, we added a quadratic function of a measure of the education cumulative distribution function (CDF) by cohort and educational attainment level to equation (1). Specifically, the "education CDF" measure for each respondent is the fraction of people in the Census born the same year with lower educational attainment than the respondent. The results, reported in columns 1 and 2 of Table 6 , show treatment effects that are on average lower by $40 \%$ and $20 \%$, respectively, relative to those reported in columns 5 and 6 of Table 3. Moreover, in column 1, the positive coefficients for both the CDF and its square imply that as the proportion of one's cohort with less schooling goes up, ability to speak English increases. In column 2, the negative coefficient for education CDF and positive coefficient of greater magnitude for its square imply that at high levels of educational attainment (such that at least $75 \%$ of one's cohort has less schooling), the higher the proportion of a cohort with less schooling, the higher is the propensity to speak English very well. This is indeed evidence of more positive selection into higher schooling when education is relatively rare.

## 2. Changing school quality

A second candidate explanation for confounding cohort-schooling trends may be changes in school quality. Increased enrollment was made possible by increased spending on school inputs (e.g., new classrooms were built, new teachers were hired, and teacher salaries were increased). At the same time, however, double enrollment - a practice in which teachers teach two half-day sessions to different groups of students to relieve overcrowding-was gradually eliminated. Double enrollment was most common in the first two grades and in rural areas; in the 1943-44 school year, for example, $78 \%$ of rural schools were on double enrollment compared with $44 \%$ of urban schools. ${ }^{14}$ Elimination of double enrollment meant more instruction time in the early grades, including in English class. This may have reduced the gap between upper- and lower-grade English proficiency among younger cohorts, thereby contributing to an educationspecific cohort trend that generates spurious reform effects.

As a rough check on the school quality story involving double enrollment, we drop those with educational attainment of grade 1-4. The only remaining members of the low-education control group, then, are people with no schooling. People with one to four years of schooling were probably most affected by the elimination of double enrollment, while people with no schooling were unaffected. The results, reported in columns 3 and 4 of Table 6, are essentially unchanged compared to columns 5 and 6 of Table 3. Likewise, results from the control experiments without grades 1-4 are similar to those from the full sample and are not reported here. Thus, the elimination of double enrollment does not appear to be behind the results in Table 3.

[^9]
## 3. Non-linearity

Because the dependent variable is binary, logit may provide a better approximation to the evolution of counterfactual outcomes than the additive specification implicit in the linearprobability differences-in-differences setup. Omitted interaction terms can arise because of the intrinsic nonlinearity in the conditional expectation function for a binary dependent variable. Therefore, as an additional check on the results in Tables 3-5, we re-estimated the regressions from columns 5 and 6 of Table 5 using logit instead of ordinary least squares. These models control for education-cohort trends. The resulting logit marginal effects are reported in columns 5 and 6 of Table 6. In practice, the logit estimates for this specification show no evidence of an effect of language reform, just as in the results from the corresponding linear probability models. Logit results are likewise similar to OLS for all other models estimated in the paper.

## 4. New schools in rural areas

In the first decades of the American occupation, few rural communities offered schooling beyond the $4^{\text {th }}$ grade. Later, however, the number of schools in rural schools increased rapidly. As a result, the urban proportion of $5^{\text {th }}$ grade enrollment fell from $66 \%$ in 1930 to $57 \%$ in 1940, and the urban proportion of $8^{\text {th }}$ grade enrollment fell from $93 \%$ in 1930 to $77 \%$ in $1940 .{ }^{15}$ Our cohort-schooling differences-in-differences strategy may be biased by the increased likelihood that more educated individuals from more recent cohorts came from rural areas and therefore had reduced English proficiency (since cities and towns present more opportunities for exposure to English in daily life).

[^10]The role of increased schooling in the countryside is difficult to control for in practice since the Census records urban/rural status only of current residence but not the birthplace. Still, an analysis based on place of residence may provide useful information so long as urban residents are more likely than rural residents to have grown up in cities and towns. Estimates by urban/rural status were constructed using data from the 1980 PUMS 5\% State and 1\% Metro samples for Puerto Rico residents, with urban defined as living in a metropolitan statistical area (MSA). ${ }^{16}$ This definition classifies $62 \%$ of the sample as urban. ${ }^{17}$

The results by urban/rural residence status are reported in Table 7. Since the sample here omits 1990 data, we also repeated the earlier analysis pooling urban and rural data as a reference point. As with the original analysis using both 1980 and 1990 data, the estimated treatment effects with 1980 data only are positive (columns 1 and 2). The urban-only results, reported in columns 3 and 4, are similar to those in the full 1980 sample. Results from the control experiments, reported in columns 5 and 6 for both urban and rural and in columns 7 and 8 for urban only, similarly show evidence of schooling-cohort trends. Thus, changes in the likelihood of urban residence for the more educated do not appear to account for these trends.

## 5. Military service

Many Puerto Ricans served in the U.S. military, especially among the older cohorts in our sample. For example, $30 \%$ of men born and living in Puerto Rico from the 1924-33 cohorts had served compared with $18 \%$ from the 1934-1943 cohorts. Veterans from these cohorts are also more educated than non-veterans. For example, among the 1924-33 cohorts, average years

[^11]of schooling were 12.5 for veterans and 6.7 for non-veterans. Military service may have increased the English-speaking ability of Puerto Ricans. Given the strong education differences by veteran status, this in turn may induce a spurious cohort-schooling trend in English.

To assess whether military service accounts for cohort-schooling trends, we re-estimated equation (1) restricting the sample to non-veteran men. The results, available on request, again show significant positive difference-in-differences estimates in both the real and placebo experiments. We also see similar results in a sample restricted to women, in spite of the fact that almost no Puerto Rican women served in the military. Thus, changes in the likelihood of serving in the U.S. military for the more educated do not appear to account for patterns observed in Table 3.

## IV. Alternative Identification Strategies

Among the five sources of cohort-schooling trends explored above, changing selection bias (based on unobserved characteristics) seems the most likely explanation for the schoolcohort trends uncovered in Tables 3-5. Although control for changes in the education CDF across cohorts does not account for all of the apparently spurious treatment effects in Table 3, allowance for changes in the distribution of schooling clearly makes a difference. As an alternative to strategies that control for unobservables using unaffected cohorts, we also experimented with an identification strategy that compares Puerto Ricans living on the mainland with immigrants from former Spanish colonies.

Especially interesting and relevant comparison groups are immigrants from Cuba and the Philippines since, like Puerto Rico, these territories became U.S. possessions in 1898. Unlike Puerto Rico, however, the language of instruction in Cuba and the Philippines has been
unchanged since the American occupation. Cuba, which became independent in 1902, has always had Spanish-only instruction in its public schools. The Philippines, which became independent in 1946, has had English instruction since occupation. We also look at two other comparison countries: the Dominican Republic, a Spanish-speaking neighbor, and Mexico, the largest source of Hispanic immigrants to the U.S. A drawback of the cross-country strategy, not shared by our first strategy, is that immigrants are self-selected and subject to U.S. eligibility rules, some of which are country-specific. An advantage, however, is that we need not rely on comparisons across schooling groups, since schooling itself is a potentially endogenous variable.

For the cross-country analysis, we focus on adult migrant and adult immigrants because they would have obtained their grades 1-12 education in their place of birth. The data are for 1990 only because year of arrival to the mainland is not available for Puerto Ricans in the 1980 census, making it impossible to drop people who would have been educated in the mainland. ${ }^{18}$ Figure 4 provides an initial look at the English-language skills of Puerto Rican migrants to the mainland relative to the immigrant control groups. This figure shows deterioration in the relative position of Puerto Ricans, especially among the mid-1930s to 1940s cohorts, though the relative position of the youngest Puerto Rican migrants appears to have improved.

To control for cohort trends that vary by country of origin, we used a regression setup similar to that used to produce the estimates in Table 5. In particular, working with a sample born 1924-63, we estimated

$$
\begin{equation*}
y_{i j k}=\alpha+\beta P R_{k} \times E_{j}+\delta P R_{k} \times E T_{j}+\theta_{j}+\rho_{k}+\pi_{k} I(j \geq 1944)+X_{i j k} \Gamma_{k}+\varepsilon_{i j k} \tag{3}
\end{equation*}
$$

for individual $i$ born in year $j$ in country $k . P R_{k}$ is a dummy variable indicating the Puerto Rican born, $E_{j}$ is dummy indicating being born 1924-33 and $E T_{j}$ is dummy indicating being born either

[^12]1924-33 or 1944-53. The coefficient $\beta$ gives a triple differences estimate, implicitly constructed by subtracting the country-of-birth trend estimated using people born 1944-63 (with those born 1944-53 in Puerto Rico taken to be pseudo-treated) from the difference-in-differences estimate for those born 1924-43 (with those born 1924-33 in Puerto Rico receiving treatment). To increase the comparability of migrants from Puerto Rico with immigrants from other countries, equation (3) also controls for individual covariates (denoted by $X_{i j k}$ ). The covariates are potential experience, years of schooling, sex and year of arrival to the mainland, with the latter three allowed to have effects $\left(\Gamma_{k}\right)$ that vary by country of birth.

The results of estimating equation (3) are presented in Table 8, which reports estimates of country-specific cohort trends, $\delta$, as well as the triple differences parameter, $\beta$. The differential trends for all three English proficiency measures are mostly positive (there are three exceptions, only one of which is significant). This suggests that the improvement in English proficiency across cohorts has been smaller for Puerto Rican migrants than for other groups (or the decline for Puerto Ricans has been larger). But because this decline relative to other immigrant groups occurred for both treated and pseudo-treated cohorts, it does not point to an adverse effect of the Puerto Rican language reform. In fact, the triple differences estimates of English instruction on all three English proficiency measures are either statistically insignificant or negative. Thus, estimates using immigrants as a control group are consistent with the earlier findings using a within-Puerto Rico identification strategy.

## V. Conclusions

Puerto Rico's 1949 language reform provides a unique opportunity to assess the long-run consequences of English-intensive instruction on the English-language skills of a Spanish-
speaking population. Perhaps surprisingly, our results suggest that the change from English to Spanish as the medium of instruction in public schools had little effect on Puerto Rican English proficiency, at least as far as self-reported English-speaking skills are concerned. These results are unexpected given the presumption by American policymakers at the time that English-only instruction was the best way to raise English proficiency among Puerto Ricans.

Our findings also contrast with those reported by Angrist and Lavy (1997), who used a similar research design to assess the effects of language reform in Morocco-in their case, a change from the colonial language (French) to Arabic in middle and secondary schools. The Angrist and Lavy results show a marked decline in French-language skills among affected groups, though it should be noted that they found a significant effect on French writing skills, but not on French reading skills. A more detailed analysis might show a similar pattern in Puerto Rico. Another likely difference between the Puerto Rican and Moroccan experiences is the relatively abundant supply of French speakers in Morocco, including French citizens and an educated workforce comfortable with a French-speaking milieu.

While our results suggest English-intensive instruction is not sufficient for improved English-language skills, there is good circumstantial evidence that English-intensive instruction is not necessary for good English-language skills either. For example, in a 2000 survey, $41 \%$ of Europeans said they knew English even though their language of instruction was a non-English mother tongue, with English taught only as a foreign language. ${ }^{19}$ Moreover, 80 percent of those surveyed in Denmark, the Netherlands, and Sweden know some English, and $60 \%$ of respondents in these countries reported "good or better" English.

The apparent disconnect between English-intensive instruction and English-language

[^13]skills has a parallel in the debate over the role of computer-aided instruction in elementary education. Angrist and Lavy (2002) found that computer-aided instruction did not improve children's math skills; in fact, traditional teaching methods appear to be more effective for mathematics instruction. Similarly, the best way to improve English skills, at least for nonnative English speakers, may be to teach English as opposed to teaching in English. Along these lines, in 2003, Chile launched a program called English Opens Doors, designed to raise English proficiency. This program focuses on teaching English as a second language in public schools (Rohter 2005). A strong presumption underlying the movement in the U.S. away from nativelanguage instruction is that children instructed in English will also speak better English. For the Puerto Rican-born, at least, this does not appear to be true.

Figure 1. English-Speaking Ability by Year of Birth for Puerto Rican-Born: 1900-1960

$\rightarrow$ Speaks English - -Speaks English Well

Notes: The sample includes 221,911 Puerto Rican-born men and women aged 30-80 from the 1980 and 1990 PUMS files for Puerto Rico and the mainland.

Figure 2. Enrollment in Puerto Rican Public Schools: 1900-1990

Notes: Enrollment rates for 1946 and earlier are from Osuna (1949), Appendix VIII, Table 2. Osuna's source is the Annual Report of the Commissioner of Education, 1945-46. Enrollment rates for 1970, 1980 and 1990 were computed by the authors using the PUMS files for those years for Puerto Rico residents.

Figure 3. Puerto Rican Education Distribution by Cohorts

Notes: The sample includes Puerto Rican-born men and women from the 1980 and 1990 PUMS files for Puerto Rico and the mainland. Each point represents the fraction of the the total number of people in that cohort at or below the indicated schooling level. The following educational attainment categories are used: 0=no schooling, 4=1 4 grades, $8=5-8$ grades, $9-12=9-12$ grades, respectively, $14=$ some college, $16=$ college degree and 18=more than college degree. Data for the 1954-63 cohort came from 1990 only.

Figure 4. English-Speaking Ability by Year of Birth for Puerto Rican Adult Migrants and Hispanic and Filipino Adult Immigrants to the Mainland: 1910-1955

Notes: The sample consists of 9,457 Puerto Rican-born adult migrants and adult immigrants from Cuba $(16,664)$, the Philippines $(15,539)$, Mexico $(41,280)$ and the Dominican Republic $(3,238)$ who arrived to the mainland between 1950 and 1979 from the 1990 PUMS files. Adult migrants and adult immigrants are defined as individuals who arrived to the mainland at age 18 or above.

Table 1. Language of Instruction Policies in Puerto Rican Public Schools

| Years | Policy |
| :---: | :---: |
| 1493-1898 | Puerto Rico was a Spanish colony throughout the period. Spanish was the medium of instruction. |
| 1898-1900 | In 1898, Puerto Rico became a U.S. territory. 1898-1900 was a transitional period in which Puerto Rico was run by military government. The official policy was English instruction, but little changed from the Spanish period. |
| 1900-1905 | Brumbaugh policy: Spanish instruction in elementary school (grades 1-8) and English in secondary school (grades 9-12). |
| 1905-1916 | Falkner policy: English instruction in all grades. |
| 1916-1934 | Miller policy: Spanish instruction in grades 1-4, half Spanish and half English in grade 5, and English in grades 6-12. |
| 1934-1937 | Padín policy: Spanish instruction in elementary school (grades 1-8) and English in secondary school (grades 9-12). |
| 1937-1942 | Gallardo policy: Spanish instruction in grades 1-2, both Spanish and English in grades 3-8 with progressive increase in English, and English in grades 9-12. |
| 1942-1945 | Revert to Padín policy: Spanish instruction in elementary school (now grades 1-6) and English in secondary school (now grades 7-12). |
| 1945-1949 | No official policy change but a gradual transition to Spanish instruction in all grades. |
| 1949-present | Villaronga policy: Spanish instruction in all grades. |

Notes: Sources were Osuna (1949) and Cafferty and Rivera-Martínez (1981). Policy names refer to Commissioners of Education. A given calendar year may have two different policies since the school year begins with the fall semester and ends with the spring semester.

 yearly up through the last grade completed. Variation from cohort to cohort comes from the policy shifts described in Table 1. We coded grade-years in which both English and Spanish were used as languages of instruction as a fraction of a whole year of treatment. Under the Miller policy, grade 5 was half Spanish and half English. Under the Gallardo policy, grades $3-8$ used both Spanish and English with a gradual increase in English.

Notes: The sample consists of individuals born 1924-43 in Puerto Rico from the 1980 and 1990 PUMS files. Each column is from a separate OLS regression controlling for year of birth dummies, educational attainment dummies (using categories defined in Figure 3), age dummies, census year dummies,
female dummy and a quadratic in potential experience (age-years of schooling-6). Years of exposure to English-intensive instruction is from Table 2, rounded to the nearest whole number. Robust standard errors are shown in parentheses. The F-test p-value reported is for a test of the joint significance of the eight years of exposure dummies.

Notes: The sample consists of individuals born and currently living in Puerto Rico from the 1980 and 1990 PUMS files. Each column is from a separate OLS regression controlling for year of birth dummies, educational attainment dummies (using categories defined in Figure 3), age dummies, census year dummies, female dummy and a quadratic in potential experience (age-years of schooling-6). Years of pseudo-exposure equals actual years of exposure as if the older cohort were born 1924-33 (which is the older cohort in Columns 1 and 2) and the younger cohort were born 1934-43 (which is the younger cohort in Columns 1 and 2).
Robust standard errors are shown in parentheses. The F-test p-value reported is for a test of the joint significance of the eight years of exposure dummies.

| Number of observations | 233,990 | 233,990 | 233,990 | 233,990 | 158,899 | 158,899 |

Notes: The sample consists of individuals born 1924-63 in Puerto Rico from the 1980 and 1990 PUMS files. Each column is from a separate OLS regression which contains as controls years of pseudo-exposure dummies and the same covariates as in Table 3. The education, age, census year, female and potential experience coefficients are allowed to vary by two groupings of year of birth, born 1924-43 and born 1944-63. Years of pseudo-exposure is equal to actual years of exposure for individuals born 1924-43. On the other hand, individuals born 1944-63 are assigned the actual years of exposure as if they were born twenty years earlier. Robust standard errors are shown in parentheses. The F-test p-value reported is for a test of the joint significance of the eight years of exposure dummies.

 Columns 1 and 2 add a quadratic function of a measure of the education cumulative distribution function (CDF). This education CDF measure gives the fraction of people of the same year of birth with less education than the individual. Columns 3 and 4 report the results of omitting those with 1 st- 4 th grade educational attainment. Columns 5 and 6 report logit marginal effects corresponding to the trend-controlled estimates in Table 5, Columns 5 and 6 . Robust standard errors are shown in parentheses. The F-test $p$-value reported is for a test of the joint significance of the eight years of exposure dummies.

Notes: The sample consists of individuals born and currently living in Puerto Rico from the 1980 PUMS files. Urban is defined as living in a metropolitan area. Each column is from a separate OLS regression controlling for year of birth dummies, educational attainment dummies (using categories defined in Figure 3), age dummies, census year dummies, female dummy and a quadratic in potential experience (age-years of schooling-6). Years of pseudo-treatment in Columns $5-8$ was assigned as if the individuals were ten years younger. Robust standard errors are shown in parentheses. The F-test p-value reported is for a test of the joint significance of the eight years of exposure dummies.

Table 8. Estimation Using Puerto Rican Adult Migrants and Hispanic and Filipino Adult Immigrants to the Mainland

Notes: The analysis uses data on Puerto Rican adult migrants and Hispanic and Filipino adult immigrants born 1924-63 from the 1990 PUMS files for U.S. residents. Adult migrants and adult immigrants are defined as individuals who arrived to the mainland at age 18 or above. Each panel of each column reports the results of a separate OLS regression controlling for year of birth dummies, place of birth dummies, educational attainment dummies (using categories defined in Figure 4), female dummy, year of arrival dummies and a quadratic in potential experience (age-years of schooling-6). The coefficients for the last five variables are allowed to vary by two groupings of year of birth, born 1924-43 and born 1944-63. Additionally, the coefficients for all education, sex and year of arrival variables are allowed to differ for Puerto Ricans. Robust standard errors are shown in parentheses.

Notes: Sample consists of individuals born in Puerto Rico 1924-63 from the 1980 and 1990 PUMS files with non-missing and non-allocated values for age, education, place of birth and English-speaking ability variables. Years of exposure to English-intensive instruction is from Table 2.

[^0]:    * We thank Chinhui Juhn and participants in the 2003 Texas Econometrics Camp for helpful comments. The views expressed herein are those of the authors.

[^1]:    ${ }^{1}$ To date, Colorado is the only state to reject an "English for the Children" initiative. Concern about the consequences for non-immigrants of mainstreaming immigrant children appears to have been a factor in this case (Mitchell 2002).

[^2]:    ${ }^{2}$ Osuna (1949) and Pousada (1999) describe early studies of the effectiveness of English instruction in Puerto Rico. The general finding is that Puerto Rican students were less proficient in English than the evaluators thought they should be, or compared with students on the mainland. These studies do not address the counterfactual question of what English proficiency would have been without the English-intensive instruction then in use.
    ${ }^{3}$ Zehler et al. (2003), using data provided by school districts, estimate that there were 4.0 million LEP students in grades K-12 in U.S. public schools in the 2001-02 school year. Different school districts have different standards for classifying a student as LEP, but all LEP students are deemed to have inadequate English skills.

[^3]:    ${ }^{4}$ See, for example, Baker and de Kanter (1981), Willig (1985), Rossell and Baker (1996), and Greene (1998) for reviews. An exception is Matsudaira (2004), who uses a regression-discontinuity design to estimate the impact of participating in bilingual education and English as a Second Language (ESL) programs compared to a mainstream, English-only classroom. Matsudaira finds no effect of bilingual and ESL program participation on math scores, and weak positive effects on reading scores.
    ${ }^{5}$ This subsection provides only a brief description of education in Puerto Rico. For more detail, see Osuna (1949) and Solís (1994).

[^4]:    ${ }^{6}$ Elementary education consisted of four years of primary and four years of middle school. Beginning with the 1941-42 school year, Puerto Rico switched to a 6-year elementary school +3 -year junior high school +3 -year high school system, mirroring changes in the U.S.
    ${ }^{7}$ Children not attending public school were more likely to be out of school than attending a private school until 1990. In Puerto Rico, most private schools are Catholic schools. Although the private school share of total enrollment has risen in recent decades - according to Census data for Puerto Rico, $10 \%$ of enrolled students aged 618 were attending private schools in 1980 and $15 \%$ were in 1990-it was low and fairly stable during the time the cohorts analyzed in this paper would have attended school. For example, the share of grade K-12 enrollment in private schools was $3 \%$ in the 1919-20 school year, $4 \%$ in 1940-41, and 5\% in 1945-46 (Osuna [1949], pp. 475-476 and Appendix VI).

[^5]:    ${ }^{8}$ Among other rural elementary schools, $22 \%$ had part-time English instruction, $61 \%$ offered English as a subject, and only $0.5 \%$ used no English. Various issues of the Report of the Commissioner of Education support the view that English continued to be used in all schools in urban areas, not just in high schools. Since the Falkner policy, English training had been a prerequisite to teach in urban elementary schools; the report for the 1926-27 school year notes: "The preparation now required for an elementary urban-school teacher is a two-year normal course after graduation from high school. These teachers hold an English graded license issued by the Department of Education, which is also attainable through free examination and University summer courses by experienced rural teachers who have attained a high standing in the profession" (pp. 24-25). The report for the 1920-21 school year states: "The regular teachers not only teach English but in English...In the first four grades Spanish is used as the medium of instruction and English is taught as a special subject but by Puerto Rican teachers. The fifth and sixth are the transition grades; some subjects are taught in Spanish and others in English. In the grammar grades and in the continuation and high schools English is used as a medium of instruction and Spanish is taught as a special subject." (p. 377). The reports for the 1919-20 and 1930-31 note that English was used to teach arithmetic in grades five and up. In the 1941-42 report, which describes changes in curricula in concert with the shift to a 6-3-3 school system, English instruction is noted for urban junior high schools and grade 9 of rural junior high schools. The 1947-48 report mentions the end of English instruction in junior high, beginning with the 1948-49 school year.
    ${ }^{9}$ Authors' calculations based on enrollment data by year, grade and urban/rural status from Osuna (1949), p. 624-25, Appendix VIII, Table 1. In 1930, schools offering post-primary grades were even less prevalent in rural areas and thus the percentage of students attending schools in urban areas was even higher: $66 \%$ of $5^{\text {th }}$ graders, $93 \%$ of $8^{\text {th }}$ graders and $100 \%$ of $10^{\text {th }}$ graders. Even by the 1951-52 school year (the last year for which we managed to get the commissioner's annual report), there were no public senior high schools in rural areas.

[^6]:    ${ }^{10}$ For 1980 , we have a $6 \%$ sample for both Puerto Rico and mainland residents (the $5 \%$ A + 1\% B PUMS samples). For 1990 , we also have a $6 \%$ sample for each ( $5 \%$ State $+1 \%$ Metro PUMS samples). Data files for U.S. residents were obtained from the IPUMS website, while data files for Puerto Rico residents were obtained from the ICPSR.
    ${ }^{11}$ The Puerto Rican census form asks: "Do you know how to speak English?" with three possible responses: "yes, with ease", "yes, with difficulty" and "no, I do not speak English". This question is asked of every respondent. The 1980 and 1990 mainland census form asks: "How well does this person speak English?" with four possible responses "very well", "well", "not well" and "not at all". This question is asked only of those responding affirmatively to "Does this person speak a language other than English at home?" We coded mainland residents speaking only English as speaking English very well. Our indicator for speaking English well is 1 for Puerto Rican residents who speak English with ease or mainland residents who speak English well or very well. Our indicator for speaking English is 1 for Puerto Rican residents who speak English with difficulty or mainland residents who speak English not well or anyone for whom speaking English well is 1.

[^7]:    ${ }^{12}$ Because the sample pools 1980 and 1990 data, the extract includes those aged 37-56 in 1980 and 47-66 in 1990. The results are invariant to modest changes in these age ranges.

[^8]:    ${ }^{13}$ Logit estimates are discussed below.

[^9]:    ${ }^{14}$ Osuna (1949), p. 291. We do not have data for both urban and rural schools for other years. In $1920,90 \%$ of rural schools were on double enrollment (Osuna 1949, p. 213).

[^10]:    ${ }^{15}$ Authors' calculations based on enrollment data by year, grade and urban/rural status from Osuna (1949), p. 62425, Appendix VIII, Table 1.

[^11]:    ${ }^{16}$ The 1990 PUMS 5\% State and 1\% Metro samples also identify residence in an MSA, but we do not pool these samples with the 1980 samples because of changes in the Puerto Rican definition of MSA.
    ${ }^{17}$ Defining an urban area as a place with a population of at least 2,500 , census tabulations show that Puerto Rico's population was $40 \%$ urban in 1950 and $67 \%$ in 1980. This way of defining urban is not available in the PUMS.

[^12]:    ${ }^{18}$ A similar analysis using 2000 PUMS data and stacked 1990 and 2000 PUMS data generates similar results.

[^13]:    ${ }^{19}$ INRA (Europe), 2000. This is based on a survey of individuals aged 15 and above in the 15 European Union countries.
