Were They Prepared for Retirement? Financial Status at Advanced Ages in the HRS and AHEAD Cohorts

James M. Poterba, Steven F. Venti, and David A. Wise

NBER Working Paper No. 17824

February 2012

JEL No. D14,D91,J14

ABSTRACT

Many analysts have considered whether households approaching retirement age have accumulated enough assets to be well prepared for retirement. In this paper, we shift from studying household finances at the start of the retirement period, an ex ante measure of retirement preparation, to studying the asset holdings of households in their last years of life. The analysis is based on Health and Retirement Study with special attention to Asset and Health Dynamics Among the Oldest Old (AHEAD) cohort that was first surveyed in 1993. We consider the level of assets that households hold in the last survey wave preceding their death. We study how assets at the end of life depend on three family status pathways prior to death— (1) original one-person households in 1993, (2) persons in two-person household in 1993 with a deceased spouse in the last year observed, and (3) persons in two-person households in 1993 with the spouse alive when last observed. We find that a substantial fraction of persons die with virtually no financial assets—46.1 percent with less than \$10,000—and many of these households also have no housing wealth and rely almost entirely on Social Security benefits for support. In addition this group is disproportionately in poor health. Based on a replacement rate comparison, many of these households may be deemed to have been well-prepared for retirement, in the sense that their income in their final years was not substantially lower than their income in their late 50s or early 60s. Yet with such low asset levels, they would have little capacity to pay for unanticipated needs such as health expenses or other financial shocks or to pay for entertainment, travel, or other activities. This raises a question of whether the replacement ratio is a sufficient statistic for the “adequacy” of retirement preparation.

Many analysts have considered whether households approaching retirement age have accumulated enough assets to be well prepared for retirement. Various methods have been used to evaluate retirement preparedness, and the range of studies that apply these methods has yielded a diverse set of conclusions. Some studies are based on comparisons between observed saving or consumption and the predictions of the life-cycle model. Others measure the ability of households to replace pre-retirement levels of income or consumption, or compare post-retirement income to poverty thresholds. Many recent studies have been based on the Health and Retirement Study (HRS), with emphasis on the original HRS cohort that was between the ages of 51 and 61 in 1992. Other studies use the Survey of Consumer Finances or the SSA's Employee Beneficiary Survey. A partial list of recent studies of retirement preparedness would include Bernheim (1992), Mitchell and Moore (1998), Engen, Gale and Uccello (1999), Haveman, Holde, Wolfe and Romanov (2005), Scholz, Seshadri and Khitatrakun (2006), Munnell, Webb and Golub-Sass (2007), Love, Smith and McNair (2008), Hurd and Rohwedder (2009), VanDerhei and Copeland (2010).

In this paper, we shift from studying household finances at the start of the retirement period, an ex ante measure of retirement preparation, to studying the asset holdings of households in their last years of life. We focus on non-annuitized assets and income. Virtually all households have a Social Security annuity, and many have a defined benefit pension annuity as well. We examine non-annuitized assets held at the end of life, in addition to income, because they can provide an ex post indicator of whether households were well-prepared for retirement. If there are substantial numbers of very old households with very low asset levels, relative to the number of households with low asset levels at the start of retirement, then many households exhausted their retirement resources. If most households still hold substantial assets at very advanced ages, or in the last few years before their death, the pattern is more difficult to interpret. It is difficult to determine whether such households had what they would have considered "sufficient" resources for retirement, and did not need to reduce their consumption outlays in late life, or if they conserved the (insufficient) resources they had throughout the retirement period.

We study the level of assets that households hold in the last survey wave preceding their death. In parts of the analysis we make use of all of the cohorts that are now part of the Health and Retirement Study. We give special attention, however, to the older Asset and Health Dynamics Among the Oldest Old (AHEAD) cohort. We calculate the level of wealth at death and offer several metrics for determining the proportion of households that may be thought of as having “insufficient assets” for their retirement. In addition to summarizing the level of assets, we also study how assets at the end of life depend on family status pathways to prior to death. We are particularly interested in the strong relationship between of health and assets near the end of life. We also give special attention to the relationship between assets and longevity after the 1993 first wave of the AHEAD cohort. We find a strong relationship between health status and wealth at death.

Our paper is divided into six sections. In the first, we show detailed balance sheets in 2008 for households by five-year age intervals—65 to 69, 70 to 74, 75 to 79, 80 to 84, and 85 and older, respectively. These balance sheets are based on households in all HRS cohorts—HRS, AHEAD, Children of Depression (CODA), War Baby (WB) and Early Baby Boomer (EBB). We find that the change in assets with age, as well as the level of assets, differs greatly between single households and married couples.

We explore this pattern further by considering the evolution of assets of the AHEAD as well as the HRS cohorts, distinguishing two-person households, one-person households, and households that transition from two- to one-person households. We emphasize the distinction between the evolution of assets between survey waves for persons who are alive in adjacent waves, and the evolution of assets with age that can be attributed to “mortality selection effects” and the progressive selection over time of households with greater financial assets and lower mortality risk. We are also careful to distinguish between death and attrition as separate reasons why persons do not remain in the sample through 2008. The selection effects we calculate are due to death and not due to sample attrition.

In the second section, we present greater detail on the evolution of wealth for AHEAD households. We distinguish three family status pathways based on family status in 1993 (the first year observed) and family status when last observed—(1) original one-person households in 1993 who were also single at death, (2) original two-person households in 1993 in which one spouse is deceased in the last year observed, and (3) original two-person households in 1993 in which both spouses remain alive in the last year observed. A fourth group—those who were single in 1993 and who later remarried—is not analyzed because of its small sample size. Within each of these groups we show the evolution of wealth by the last year observed (LYO), which is the last wave prior to death for those who die or 2008, the most recent survey wave available, for those who are still alive in that year. We highlight the strong relationship

between wealth in 1993 and subsequent longevity. We consider several components of wealth—total wealth, financial assets including personal retirement accounts, housing wealth, and annuity wealth including both Social Security benefits and defined benefit pension benefits. We also report information on an indicator variable for whether the household owns a home.

In the third and fourth sections, we present results for the single-person family pathway group. We focus attention on this group because it is the largest of the three pathway groups and because it is the group most likely to have low wealth prior to death. In section three, we present estimates of the relationship between wealth and age, and between wealth and health, with separate estimates of the health and age effects for each LYO. The health measure we use is similar to the index developed in Poterba, Venti, and Wise (2010a, 2010b). Using the regression estimates we predict assets by health and age interval and by LYO. In section four, we show the distribution of assets by asset category within each health quintile and age interval. We also suggest metrics to help to put the results in context.

In the fifth section, we present data for all family pathway groups combined and we compare results across all three family pathways. The last section summarizes and concludes.

1. Balance Sheets and Evolution of Non-Annuity Wealth by Family Status

Table 1-1 summarizes information in the HRS on household balance sheets for three age groups and for five aggregated asset categories—financial assets (balances in taxable financial assets as well as balances in IRA plans, Keogh plans, 401(k) and similar plans), equity in the primary home, other non-annuity assets (the net value of other real estate, equity in second homes and business assets less non-housing debt), the expected present discounted value of Social Security and defined benefit pension benefits, and net worth (total wealth). These balance sheets are based on households in all HRS cohorts—HRS, AHEAD, Children of Depression (CODA), War Baby (WB) and Early Baby Boomer (EBB). The data on 401(k) balances in these tables are incomplete because respondents in the two oldest cohorts, CODA and AHEAD, were not asked for their 401(k) balances. However, these cohorts were unlikely to have substantial accumulations because they left the labor force before or shortly after 401(k) accounts became available in 1982. Members of the CODA cohort were age 68 to 74 when first surveyed in 1998 and members of the AHEAD cohort were age 70 and older when first surveyed in 1993. Appendix Tables 1a through 1e show detailed balance sheets in 2008 for households by five-year age intervals—65 to 69, 70 to 74, 75 to 79, 80 to 84, and 85 and older respectively. Separate panels are shown for all households as well as for one-person and two-person households. Data are shown for both means and medians.

Table 1-1. Balance sheets for households in 2008, by age and marital status						
Asset Category	Single-Person Households			Two-Person Households		
	% of Households with Asset	Median Holding	Mean Holding	% of Households with Asset	Median Holding	Mean Holding
aged 65 to 69 in 2008						
Financial Assets	84.2	12,500	130,156	92.6	111,600	354,455
Home Equity	65.9	52,000	107,483	91.1	150,000	232,300
Other Non-annuity Assets	18.8	0	96,357	38.8	0	171,441

Net worth	99.1	414,435	649,161	99.6	1,015,317	1,375,963
aged 75 to 79 in 2008						
Financial Assets	86.4	13,000	128,522	93.9	112,500	331,901
Home Equity	65.7	60,000	123,144	88.9	151,000	228,371
Other Non-annuity Assets	15.2	0	47,447	31.7	0	198,979
PV of Social Security and DB Pension Benefits	99.0	200,303	243,304	99.9	460,509	525,772
Net worth	99.4	336,058	542,416	100.0	858,331	1,285,024
aged 85 or older in 2008						
Financial Assets	88.6	22,000	152,958	91.8	125,000	332,631
Home Equity	54.1	35,000	101,728	84.8	125,000	210,917
Other Non-annuity Assets	13.3	0	45,294	28.2	0	155,145
PV of Social Security and DB Pension Benefits	99.0	82,855	108,582	99.7	224,317	284,348
Net worth	99.7	214,371	408,562	100.0	674,965	983,042

Several features of the summary data in Table 1-1 warrant comment. First, whether measured by medians or means, the net worth of older households, even those aged 85 and older, seems rather large. The net worth of two-person households is more than twice as large as the net worth of one-person households. Median (mean) total net worth for households aged 65 to 69 is \$414,435 (\$649,161) for singles and \$1,015,317 (\$1,375,963) for couples in 2008. Net worth is lower at older ages, in large part because of the decline in expected present value of benefits from Social Security and defined benefit pensions. Wealth from these sources is lower for older households than for younger households because expected payments from these sources are weighted by survival probabilities.

We do not focus on cross-age comparisons in the balance sheets. The pattern of levels across ages depends on at least two competing effects: assets are lower for older households because of "cohort effects" (older generations had

lower lifetime earnings, on average, than younger generations) and assets are higher for older households because of "mortality effects" (on average, within each cohort, poorer households die at younger ages). We give special attention to mortality effects in the subsequent analysis.

The largest components of non-annuity net worth are housing wealth and financial assets (including personal retirement accounts). Of single person households, 66 percent of those aged 65-69 own homes and this rate remains about the same for nearly twenty years; for the group aged 85 and older, the rate drops to 54 percent. About 91 percent of married couples aged 65-69 own homes. Thereafter the rate drops gradually to about 89 percent for ages 75 to 79 and 85 percent for those aged 85 and older.

Asset Category	percentile	Single-Person Households			Two-Person Households		
		age 65 to 69	age 75 to 79	age 85 or older	age 65 to 69	age 75 to 79	age 85 or older
Financial Assets	10	0	0	0	300	450	750
	25	300	500	1,300	13,500	11,000	27,000

	90	610,166	410,850	196,096	1,155,331	840,320	478,903
Net worth	10	157,921	123,191	56,266	346,946	388,174	223,847
	25	237,154	193,157	93,411	609,949	566,980	350,801
	50	414,435	336,058	214,371	1,015,317	858,331	674,965
	75	778,662	662,494	470,768	1,660,631	1,443,753	1,177,966
	90	1,291,336	1,155,530	1,051,622	2,582,332	2,279,724	1,821,628

Table 1-2 shows selected percentiles of the distribution of assets. It demonstrates that a large proportion of households have very few, or no, liquid financial assets. This is especially true for single-person households. The 25th percentile of financial assets for singles is less than \$1,300 for all age groups. Many single-person households also have no home equity. The 25th percentile is zero for all age groups. In addition, a large fraction of both single- and two-

person households have no other non-annuity assets. The 75th percentile is zero for single-households at all ages and the 50th percentile is zero for two-person households at all ages.

Recall that the balance sheets pertain to the wealth of those who survive to each age. In contrast, Figures 1-1 and 1-2 show the evolution of assets by family status—two person households, one-person households, and households that transition from two- to one-person households during the interval between survey waves—for HRS and AHEAD households respectively. The figures exclude persons in households that transitioned from one-person to two-person because the sample sizes for this group were too small to give reliable results. Wealth includes all assets reported in Table 1-1 except Social Security wealth, defined benefit pension wealth, and 401(k) balances. For the HRS cohort, 401(k) balances are not included because of missing data in some of the early years, as discussed in Venti (2011). Balances in 401(k) accounts were not collected in the AHEAD.

Figure 1-1 shows the wave-to-wave change in median non-annuity wealth in the three family status groups for HRS households. All values are converted to 2008 dollars using the CPI. For example, the median wealth of persons who remained in two-person households between 1992 and 1994 (labeled as "2 to 2") increased from about \$184,000 to \$213,000. For those who remained in two-person households between 1994 and 1996, median wealth increased from about \$223,000 to \$231,000. In all intervals, wealth increased for persons in continuing two person households.

It is important to distinguish between the within-interval changes in wealth shown by the line segments in the figure and the effect of differential mortality indicated by the vertical height of the "gaps" between segments. To illustrate this point, note that persons in two-person households present in both the 1996 and 1998 waves had \$243,706 in wealth in 1998, but that persons in two-person households present in both the 1998 and 2000 waves had \$254,419 in 1998. This difference is circled in the figure. The difference between \$243,706 and \$254,419 is the "selection" effect—two-person households that dissolved because of death of a spouse, divorce or separation between 1998 and 2000 had lower wealth in 1998 than those who continued as two-person households through the 1998 to 2000 period.

To understand the evolution of wealth with age, as distinct from the selection effect, it is important to focus on the wave-to-wave changes (segment slopes). For two-person households in the HRS who were between the ages of 51 and 61 in 1992, the wave-to-wave changes are positive in all intervals. The increase in wealth for persons in continuing two-person households can be seen by tracking the assets in the first year of each interval. Some component of this increase is due to the progressive selection of households with greater wealth. For one-person households wealth increased in all but two wave-to-wave

intervals. The mortality selection effects are not so apparent for single-person households, in part because a large fraction of one-person households had relatively low wealth, with median levels between \$50,000 and \$100,000 over the 1992 to 2008 period.

Figure 1-1 also shows that the non-annuity wealth of persons in two-person households that dissolve between waves declines substantially. This is observed in each of the intervals. The assets of persons in two- to one-person households were also much lower at the beginning of an interval than the assets of persons in continuing two-person households. After dissolution, however, the wealth of the surviving single persons was still larger than the wealth of continuing one-person households.

Figure 1-2 shows the evolution of non-annuity wealth for persons in AHEAD households. The data for 1993 are omitted from the figure because, as Rohwedder, Haider, and Hurd (2006) explain, financial assets were under-reported in AHEAD in that year. For the AHEAD households, the mortality selection effects are extremely important (circles in the figure). Persons who continued in two-person households from one interval to the next typically held much greater wealth balances than those who did not. For AHEAD households, the within-interval change in wealth for persons in continuing two-person households was negative in all but the first interval, 1995 to 1998. The wealth of continuing one-person households declined in each period. For AHEAD households the decline in the wealth for persons in two-person households that dissolved during an interval is similar in magnitude to the decline for persons in continuing two-person households. For these households dissolution was primarily the consequence of mortality, whereas for HRS households dissolution was more often the consequence of divorce or separation. As with the HRS cohort, the level of wealth of persons in two-person households that dissolved during an interval was much lower than the level of wealth of persons in continuing two person households. Among persons in households that dissolved in an interval the wealth of the surviving spouse remained much higher than the wealth of continuing one-person households.

In short, the figures show the within interval change in the wealth of households that survive over the interval, but they also make clear that some of the change from interval to interval is due to the progressive selection of households with greater wealth. This effect plays a key role in the subsequent analysis.

Figure 1-1. Median non-annuity wealth of persons in the HRS, by family status

Figure 1-2. Median non-annuity wealth of persons in the AHEAD, by family status

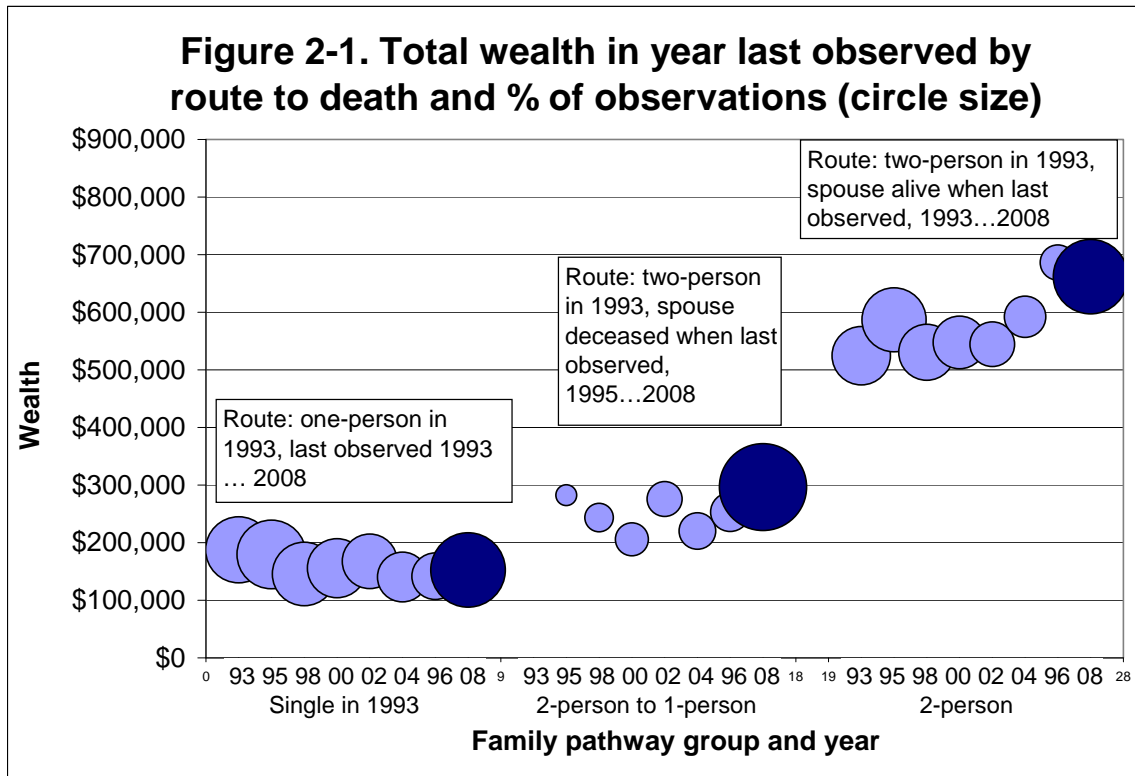

2. The Evolution of Wealth for AHEAD Households

The remainder of the paper focuses on AHEAD households. The goal is to describe the evolution of wealth by family pathway group and by asset category from 1993 to 2008 and to consider the wealth of persons in the last year observed (LYO). All persons last observed in years before 2008 are known to be deceased--persons who leave the sample but are not known to be deceased are excluded from the analysis. Persons whose last year observed is 2008 are not deceased. Most waves are spaced two years apart, with the exception of a three year gap between the 1995 and 1998 waves. Thus for persons who have an LYO before 2008, the last observation may be up to two years before the actual date of death (or three years if the LYO is 1995.)

We begin by dividing the AHEAD respondents into three groups defined by family status when first observed in 1993 and family status in the LYO. These groups, which we call "family pathway groups," are: (1) original one-person households in 1993, (2) persons in two-person household in 1993 with a deceased spouse in the last year observed before death, and (3) persons in two-person households in 1993 with the spouse alive when last observed. For shorthand we sometimes refer to the groups as one-person, two-person to one-person, and two-person respectively. A fourth group of persons, in a one-person household in 1993 and in a two-person household when last observed, is excluded because this group is too small for meaningful analysis. Also, all persons who joined the AHEAD sample after 1993 are excluded. Some persons in one-person households in 1993 may have been in two-person households prior to 1993. Figure 2-1 is a graphical description of the total wealth (including the present values of Social Security and DB pension benefits) and the relative size of each of these groups in each LYO. For each family progression group, the location of each circle indicates the level of median wealth (shown on the vertical axis) and the associated LYO (shown on the horizontal axis). The size of each circle indicates the percent of the total sample in each LYO group accounted for by the particular sub-group.

In each family progression group, the wealth and the percent of persons last observed in 2008 (not deceased) is represented by the dark blue circles. The other circles indicate wealth in the last wave prior to death. One-person households in 1993 died with the least wealth, between \$142,000 and \$188,000 at the median. Those in two-person households in 1993 with a spouse alive when they died had the greatest wealth in the wave prior to death, between \$585,000 and \$685,000. Those in two-person households in 1993 whose spouse was deceased when last observed had median wealth in the wave prior to death between \$206,000 and \$286,000.

A general feature of the data is the strong and consistent relationship between wealth in 1993 and survival, the year a person is last observed in the data. Among persons first observed in 1993, those who will die the earliest begin with the lowest assets in 1993. The relationship holds for all asset categories. Figure 2-2a shows the relationship for three of the four asset categories shown in Table 1-1—annuity wealth, home equity, and financial assets—for each of the family progression groups. The figure shows medians for each asset category in 1993. The fourth category in Table 1-1, other non-annuity assets, is not shown because the median is zero in all years for all groups. Because medians are used in the figure, the stacked vertical height of the bars in the figure is not equal to median total wealth. Figure 2-2b shows means for all four categories. In the subsequent discussion we often show medians and not means.

For each of the groups, Social Security and defined benefit pension wealth is by far the largest wealth holding. The relationship between wealth when first observed and subsequent mortality is striking. For example, the rising profiles within each group shows that annuity wealth in 1993 is higher for persons who die prior to the 2000 wave (whose LYO is 1998) than for persons who die prior to 1998 wave (whose LYO is 1995). Similarly persons who die prior to the 2002 wave have higher annuity wealth in 1993 than persons who die prior to the 2000 wave, and so forth. Similar patterns are evident for the home equity and financial assets. The wealth-mortality gradient that has been widely observed by others is strongly evident in these data. Examples of previous studies that have found

strong positive correlation between wealth and longevity include Smith (1999, 2004, 2005), Adams et. al. (2003), Wu (2003), Michaud and van Soest (2008), Case and Deaton (2009), Attanasio (2003), and Hurd and McFadden (2001).

Figure 2-2a. Median annuity wealth, home equity, and financial assets in 1993 by family route and last year observed

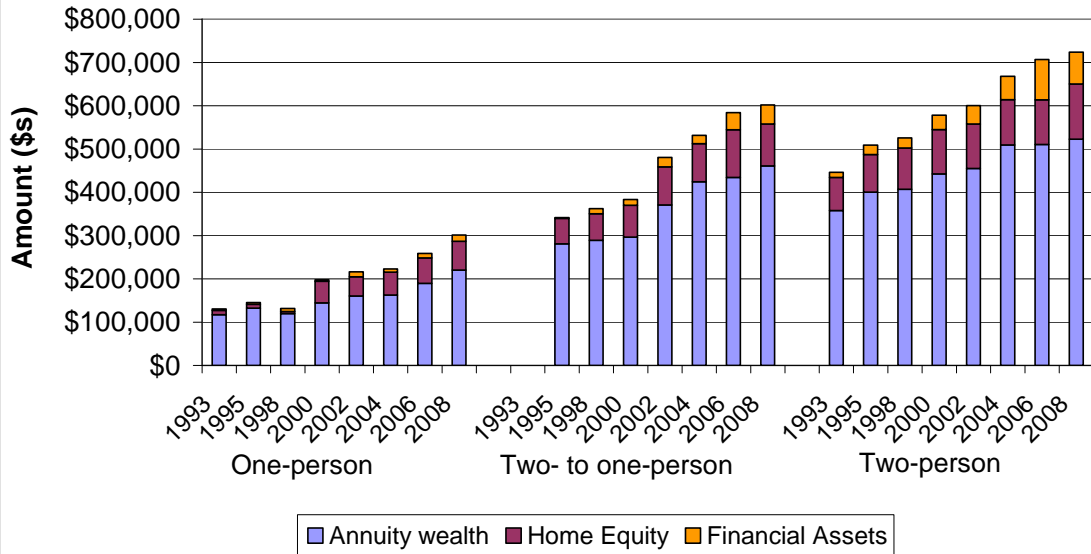

Figure 2-2b. Mean annuity wealth, home equity, financial assets, and other wealth in 1993 by family route and last year observed

We do not address the direction of causality between health and wealth or between wealth and mortality although here and elsewhere in the paper we often implicitly assume that health is given and subsequent outcomes follow. This assumption is consistent with the findings of Smith (1999, 2004, 2005), Adams et al. (2003), Wu (2003), Michaud and van Soest (2008), and Case and Deaton (2009). The general consensus is that that causation from health to wealth is the dominant pathway at least in the U.S. but there is no universal agreement.

The figure above shows that persons "closer" to death in 1993 have lower assets in 1993 than those who will live longer. We can see the same pattern over time by showing how assets evolve over time for groups of persons identified by the last year observed in the sample. Again, an LYO of 2006 or earlier indicates that the person died in the two-year interval following the LYO. An LYO of 2008 indicates that the person is still alive in 2008, the last year of our sample. The next series of figures show the evolution of assets for several wealth sub-categories—total wealth, financial assets (including IRA and Keogh accounts), home equity, Social Security wealth, and defined benefit pension wealth. We also show the percentage of households who own their homes and the evolution of total income. There is one figure for each wealth category, with data for each of three family pathway groups. For each figure the evolution of median wealth is shown by LYO.

Figure 2-3 shows median total wealth for the three family pathway groups. Total wealth in 1993 is lowest for the first family pathway group (one-person households) and highest for the third pathway group (two-person households with a spouse alive when last observed). In each of the groups, total wealth in 1993 is very strongly related to the LYO. Those who live longer have higher wealth. In addition, total wealth typically declines as persons get "closer" to death for each of the groups, largely because of the mechanical decline in annuity wealth. But the decline is much slower for the for persons in two-person families who have a spouse alive when last observed, a group that also has much greater wealth in 1993.

Figure 2-4 shows the evolution of financial assets (including IRA and Keogh accounts) for the three pathway groups. The vertical line between 1993 and 1995 is a reminder that some financial assets were under-reported in 1993, although we present the data because IRA and Keogh assets are not underreported. Again, the financial assets of the first group decline quite systematically after 1995 and the financial assets of the second group typically decline as well, at least after 1998. The decline is in part induced by the minimum distribution requirement for 401(k) and non-Roth IRA accounts. Nonetheless, there is much less decline in the financial assets of the third pathway group.

Figure 2-5 shows the evolution of home equity. For one-person households the data show a very sharp decline in median home equity beginning two or three years before death. Indeed for each LYO, median home equity in the wave prior to death was zero for all but those whose LYO was 1993. For original two-person households with the spouse deceased at the LYO, a sharp decline near the end of life is also apparent, although the median at death is zero only for those whose LYO was 2002 or 2004. For original two-person households with the spouse alive at the LYO, there is a decline in home equity in the year or two before death, but it is more modest than that for the previous two groups. Home equity declines relatively little in prior years for this group. The results are consistent with the findings of Venti and Wise (2002, 2004) who emphasize that home equity tends to be husbanded until a precipitating shock such as entry to a nursing home or death of a spouse.

Figure 2-6 shows the evolution of home ownership rates. The decline in ownership seems more consistent over time than the decline in housing wealth for all family pathway groups. Housing wealth typically declined sharply near the end of life. The decline in ownership between 1993 and the year last observed was greatest for the one-person and the two- to one-person family groups. For the one-person group the decline ranged from -3.4 percent for persons whose LYO was 1995 to -39.9 percent for persons whose LYO was 2006. For the two- to one-person group, the decline ranged from -0.1 percent for persons whose LYO was 1995 to -31.6 percent for persons whose LYO was 2006. For the two-person group, however the decline was less than three percent through 2000 and then ranged from -6.9 percent for persons whose LYO was 2002 to -11.5 percent for persons whose LYO was 2006.

The evolution of Social Security wealth is shown in Figure 2-7. The pattern of decline for each group is a mechanical feature of the way annuity wealth is calculated: benefits in each future year are weighted by the probability of survival. As an individual ages, the present value of remaining benefits declines because the probability of surviving for any number of years declines. Like each of the other wealth categories, the Social Security wealth data show that wealth in 1993 is very strongly related to year of death. The data also show that one-person households have substantially less Social Security wealth in 1993 than persons in the second pathway whose spouse had died before the YLO, who in turn have less wealth than the third pathway group, persons in two-person households whose spouse is alive when last observed. These data are consistent with the large literature cited earlier showing the strong relationship between measures of SES such as lifetime earnings (the primary determinant of Social Security benefits) and mortality.

Figure 2-3. Median total wealth by family progression group and last year observed

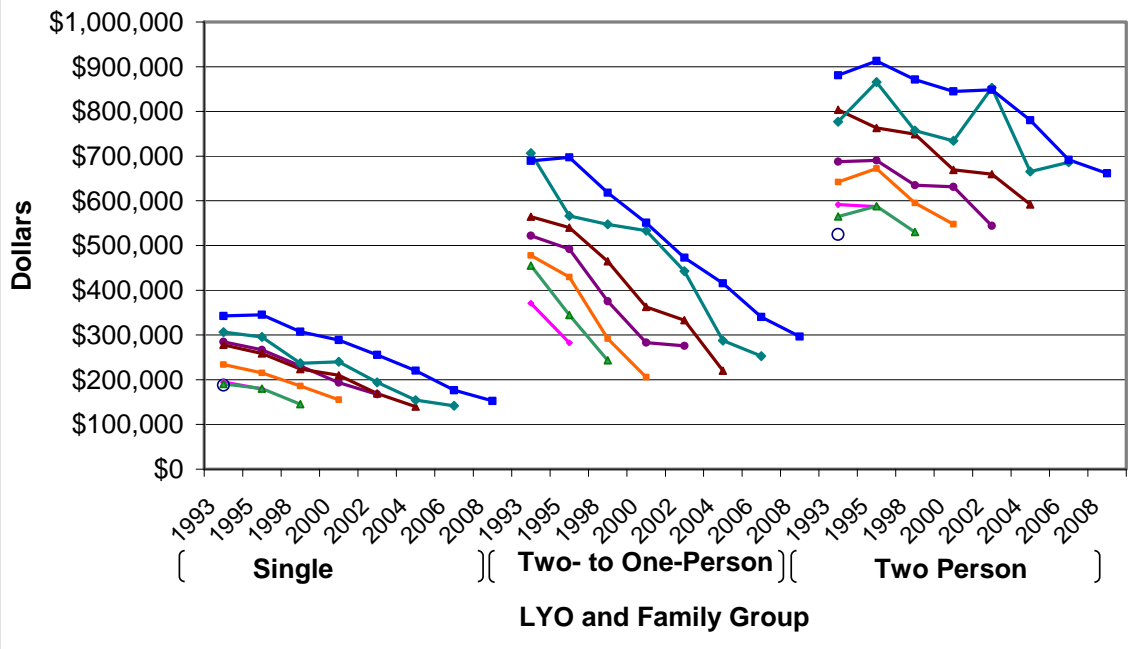

Figure 2-4. Median financial wealth by family progression group and last year observed

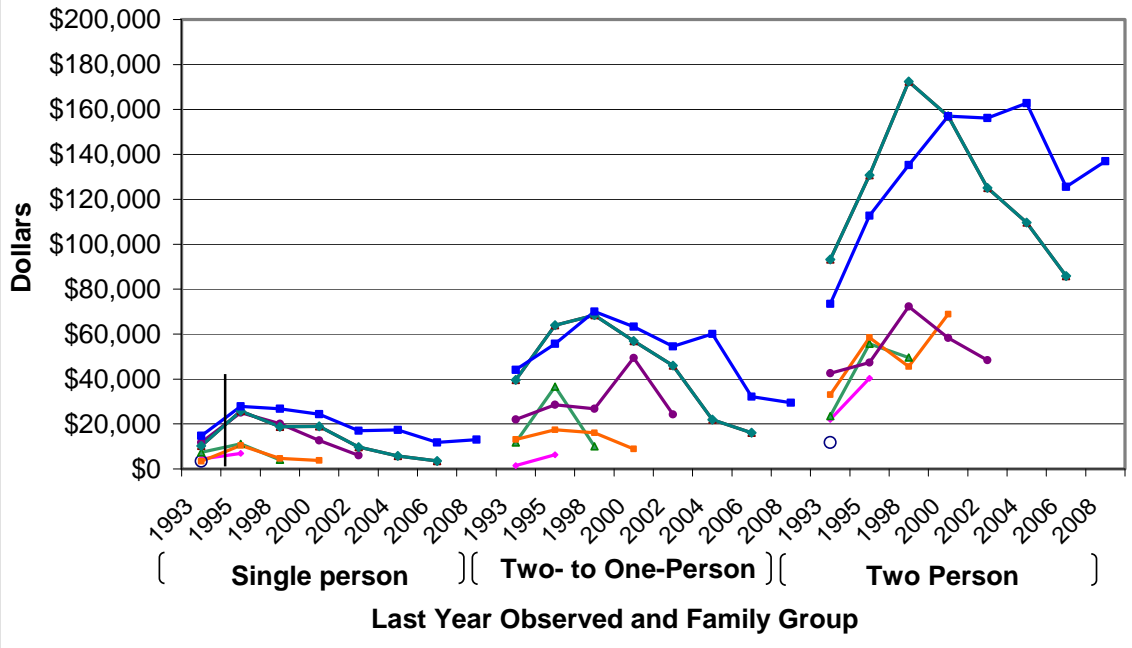

Figure 2-5. Median housing wealth by family progression group last year observed

Figure 2-6. Home ownership rate by family progression group last year observed

Figure 2-7. Median Social Security wealth by family progression group last year observed

Figure 2-8. Median DB wealth by family progression group last year observed

Figure 2-8 shows the evolution of defined benefit pension wealth. Single persons in the first pathway group essentially have no DB pension wealth. The median is zero for all one-person households except for those who survive to 2008. But persons who were in two-person households in 1993 with the spouse deceased by the LYO do have substantial median DB wealth in 1993 and persons in two-person households in 1993 with the spouse alive in the LYO had even more DB wealth. Most of the persons in the second group had zero or close to zero DB wealth at death, but persons in the third group still had noticeable DB wealth at death. Part of the explanation for the very low level of DB wealth among persons in the two-person to one-person group apparently lies with the waiver of survivorship benefits. ERISA (1974) requires employers to offer joint and survivor annuities as the default option and the Retirement Equity Act (1984) requires written consent to waive survivor benefits. Nonetheless, Johnson, Uccello, and Goldwyn (2005) report that in 2000, 28 percent of men and 69 percent of women covered by DB plans had waived survivor benefits. Even if survivor benefits are not waived, the surviving spouse's benefit is often less than 100 percent of the deceased's benefit. The implications of the husband's death for the finances of widows is discussed further in Hurd and Wise (1989), Weir and Willis (2000), and Sevak, Weir, and Willis (2003)

Finally, Figure 2-9 shows the evolution of total household income for persons in each of the three pathway groups. We will discuss the level and path of total income in more detail in the next section, but we include the pathway figure here because it is in the same format as the figures for asset categories.

The figure shows little decline for the one-person group, a modest decline for the two-person group, and a substantial decline for the two to one-person group. The percent decline between 1993 and the year last observed is shown in Table 2-1. As might be expected, the decline is especially large for persons in the two-to one-person family pathway group. For persons last observed in 2008 the decline is -48.5 percent.

Family pathway group	Year last observed						
	1995	1998	2000	2002	2004	2006	2008
One-person	4.4%	5.7%	0.5%	-2.3%	-10.8%	-14.5%	-17.6%
Two- to one-person	0.4%	-8.9%	-17.1%	-27.4%	-36.9%	-42.4%	-48.5%
Two-person	0.6%	5.0%	-7.2%	-5.3%	-14.0%	-19.1%	-19.2%

3. The Effect of Health and Age: The Single-Person Pathway

In the previous section we emphasized the strong relationship between wealth in 1993 and the time until death. In this section we emphasize the relationship between wealth and health, given the year last observed, and we draw attention to the strong relationship between health and wealth just prior to death.

We begin by using a simple median regression framework to describe how the level of assets in the last year observed depends on age and health. For each person we construct an index of health based on the first principal component of responses to 27 health-related questions contained in AHEAD. These questions asked about functional limitations, the presence of health conditions and other indicators of overall health. The list of questions used to construct the index and a discussion of the properties of the index are reported in Poterba, Venti and Wise (2010b). There are two differences between our approach in the current paper and that in our past work. First, the earlier paper constructed an index for each wave using information from the contemporaneous and all preceding waves. The index used here only uses contemporaneous wave information. Many of the questions are of the form "have you ever experienced" a health condition, so there is little extra information obtained by using prior wave information. Second, the principal component estimates varied little from wave to wave, so in the present analysis we have pooled the waves.

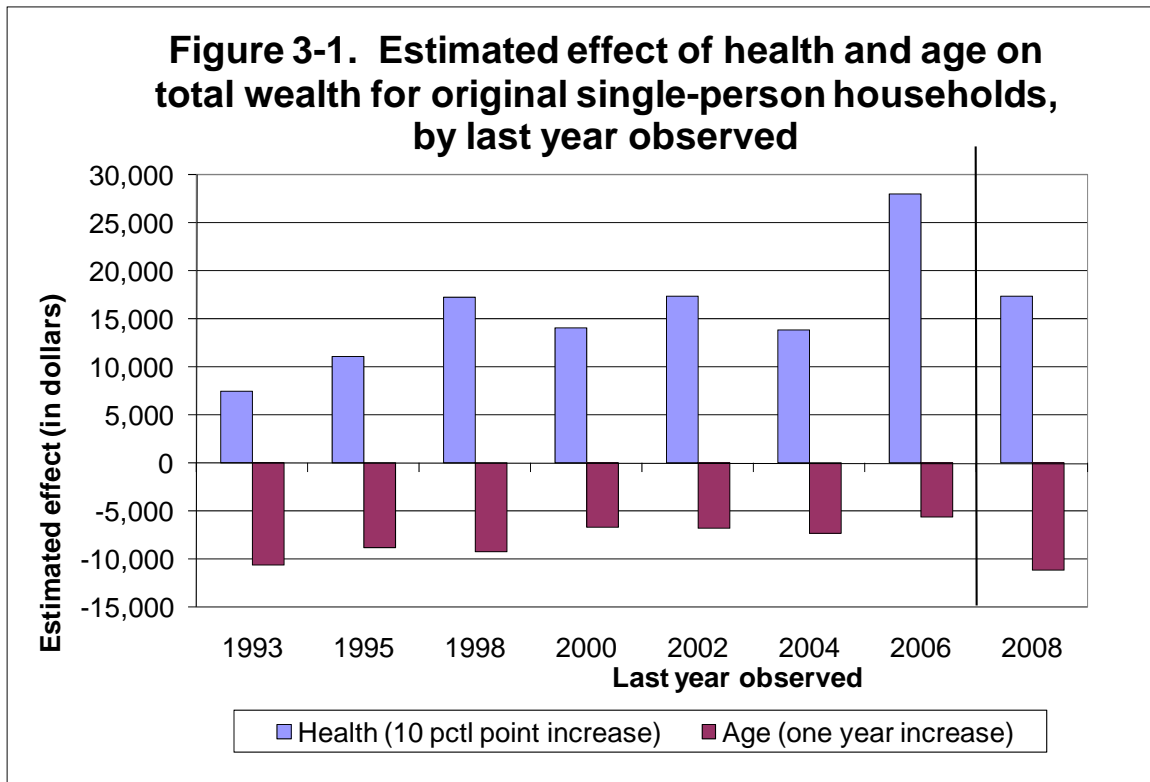

Table 3-1. Median regression estimates of the effect of health and age on wealth in the last year observed for single-person households

Variable	coeffi-cient	std error	t-stat
Last year observed			
1995	-157,361	132,956	-1.18
1998	-147,607	142,618	-1.03
2000	-361,097	163,023	-2.22
2002	-342,259	172,101	-1.99
2004	-301,661	202,467	-1.49
2006	-463,905	232,967	-1.99
2008	39,185	188,511	0.21
Effect of health in each year			
1993	753	324	2.32
1995	1,109	310	3.58
1998	1,730	371	4.67
2000	1,412	355	3.98
2002	1,738	425	4.09
2004	1,390	436	3.19
2006	2,800	508	5.51
2008	1,734	267	6.49
Effect of age in each year			
1993	-10,596	1,096	-9.66
1995	-8,811	1,120	-7.87
1998	-9,236	1,252	-7.38
2000	-6,652	1,528	-4.35
2002	-6,737	1,636	-4.12
2004	-7,275	1,986	-3.66
2006	-5,570	2,377	-2.34
2008	-11,125	1,810	-6.14
Constant	1,046,502	91,989	11.38
N=3,003 and pseudo R ² =0.0562			

In the median regression estimates below, we use percentiles of the index where the first percentile is the poorest health and the 100th percentile corresponds to the best health. The index used pertains to health in the last year observed. We present estimates of the effect of health and age on wealth in the LYO, with separate estimates of the health and age effects for each LYO.

Table 3-1 shows median regression estimates for the single-person pathway group. The age and health effects are statistically significant for all LYOs. The estimated effect of a 10 percentile increase in health and the effect of

an additional year of age are graphed in Figure 3-1. The effect of health on wealth in the last year observed is substantial. The estimated effect of an increase of 10 percentile points in health ranges from \$7,530 in 1993 to \$28,004 in 2006. Thus persons who have better health when last observed prior to death have much more wealth. Recall that these estimated effects are conditional on YLO, which is also related to health. For persons last observed in 2008, the estimated health effect is \$17,340. The effect of an additional year of age on wealth ranges from -\$10,596 in 1993 to -\$5,570 in 2006. The age effect is -\$11,125 for those who are last observed in 2008. Those who are last observed in 2008 have substantially more wealth than those who die before 2008.

To get an idea of how much wealth in the LYO varies by health and age, we use the estimated effects from the median regression to predict total wealth for selected health percentiles and for selected ages. Table 3-2 shows predicted total wealth for every other LYO between 1993 and 2006. The estimates show the very large effects of health, as well as age, on wealth in the LYO. The pattern is quite similar in each of the LYO panels.

These results suggest that persons who die at older ages and in poorer health are likely to die with less wealth than persons who die young and in good health. We are particularly interested in the proportion of people that die with little wealth. Without trying to define what “little” is, we begin by calculating selected percentiles of total wealth and selected categories of wealth in the last year observed by health quintile and by age interval. Unlike the previous table,

these percentiles are based on actual data rather than predictions from the median regression.

Table 3-2. Predicted wealth by last year observed, health, and age for original single person households.					
Health percentile	Age				
	70	75	80	85	90
last year observed: 1993					
10	312,294	259,313	206,331	153,349	100,368

90	389,140	355,457	321,775	288,092	254,409
last year observed: 2006					
10	220,711	192,861	165,012	137,163	109,314
30	276,718	248,868	221,019	193,170	165,321
50	332,725	304,876	277,026	249,177	221,328
70	388,732	360,883	333,033	305,184	277,335
90	444,739	416,890	389,041	361,191	333,342

Table 3-3 shows the percentiles combining all LYOs between 1993 and 2006 (the LYOs associated with death) for original single-person households. One cell in the lower left is blank because it contains fewer than 10 observations. The small cell size reflects the fact that the young and healthy are least likely to die. The shaded cells help to identify cell entries with less than \$100,000 of wealth. There are 24 such cells. All are for persons older than age 80 and 21 of the 24 are for person 85 and older. Seventeen of the 24 are for persons in the bottom 3 health quintiles and 12 of 24 are for persons in the bottom two quintiles. Only 7 are for persons in the top 2 health quintiles. Thus dying with "little" wealth is clearly concentrated among older persons who are also less healthy.

Table 3-3. Selected percentiles of the distribution of total wealth by age interval and health quintile for original single-person households, based on actual data.							
Health quintile	Percentile	Age Interval					All
		70-74	75-79	80-84	85-89	90+

Table 3-4, shows the distribution of annuity wealth in the last year observed before death by health quintile and age interval. Levels less than \$50,000 are highlighted. The decline in annuity wealth by age is largely mechanical and is reflected in the concentration of low annuity wealth among persons who are aged 90 or older. But the differences across health quintiles indicate the large differences in percentiles by health status. For example, over all age intervals, the 25th percentile ranges from \$49,795 for persons in the lowest health quintile to \$119,704 for persons in the top quintile.

Table 3-4. Selected percentiles of the distribution of annuity wealth by age interval and health quintile for original single-person households, based on actual data.

Health quintile	Percentile	Age interval					All

Table 3-5 shows the distribution of non-annuity wealth by health quintile and by age interval. A large fraction of single-person households have essentially no non-annuity wealth, particularly those in the bottom two health quintiles. In these health groups, the 25th percentile is zero or close to zero for all age intervals. Even for the higher health quintiles the 10th percentile is zero averaged over all age intervals.

Table 3-5. Selected percentiles of the distribution of non-annuity wealth by age interval and health quintile for original single-person households, based on actual data.

Perhaps a better way to judge whether persons have "low" resources at death is to look at resources immediately available for day-to-day expenses. Table 3-6 shows the distribution of total income in the last year observed before death by health quintile and age interval.

Table 3-6. Selected percentiles of the distribution of total income by age interval and health quintile for original single-person households, based on actual data.

Total income includes benefits from Social Security and defined benefit pension plans, government transfer income, and dividends, interest payments, rent received and other income from assets. Again, the relationship between health and income is quite pronounced. Even controlling for age and health, total income varies considerably within each cell. The 90th percentile is typically at

least four times as large as the 10th percentile. Of particular interest is the association between health and total income summarized in the last column. The 10th percentile of total income is surprisingly similar across all levels of health—between \$7,342 for persons in the lowest health quintile and \$8,718 for persons in the top health quintile. However, health has a more depressive effect at higher percentiles. The 90th percentile of total income for persons in the poorest health quintile is only \$32,541, but the 90th percentile for persons in the top health quintile is \$61,494.

We next consider summary measures of financial resources that focus on the joint distribution of annuity income and liquid financial assets. The top panel of Table 3-7 shows the selected points on the bivariate cumulative distribution of annuity income and liquid financial assets (including IRA accounts) in the LYO (again combining all LYO between 1993 and 2006). For convenience, the diagonals are shown in bold. The upper-left entry in the table shows, for example, that 12.1 of single-person households have less than \$10,000 in annuity income and no financial assets in the last year observed. The entry below it shows that 23.9 percent of households have less than \$10,000 in annuity income and less than \$10,000 in financial assets. More than half of all households (57 percent) have less than \$10,000 in financial assets in the last year we observe them. As a point of reference, the 2008 poverty threshold for single persons aged 65 and older is about \$10,000. The table also shows that 52.0 percent of single-person households have annuity income less than \$20,000 (about twice the poverty level) and financial assets less than \$10,000. Although not shown in the table the percent of single-person households with annuity income less than \$15,000 (about one and one-half time the poverty level) and financial assets less than \$5,000 is 39.6 percent. Over all financial asset levels, 31.9 percent had annuity income less than \$10,000 and 82 percent of households had less than \$20,000 of annuity income. Of this latter group, 23 percent also has no financial assets.

Home equity is an illiquid asset that households tend to hold through late life. Venti and Wise (2004) and several other studies find that households typically sell their homes only when confronted with a precipitating shock to family structure, like death of a spouse or entry into a nursing home. By the time single-person AHEAD households approach the last year observed, many have divested their housing wealth, as shown in earlier in Figure 2-5.

Table 3-7. Selected characteristics of single-person households, by annuity income and financial assets in the last year observed before death

Percentage distribution

All	25.1	28.4	29.5	33.4	28.5

The middle panel of Table 3-7 shows the proportion of single-person households with zero housing wealth (including persons with negative home equity) by annuity income and financial asset intervals that are comparable to the cumulative levels in the first panel. For example, of persons with annuity income less than \$10,000 and no financial assets, 76.3 percent have no housing wealth. Of persons with \$30,000 to \$40,000 in annuity income and \$25,000 to \$50,000 in

financial assets, 47.0 percent have no housing equity. Overall, 57.1 percent of persons in the single-household family pathway have no housing equity in the last year observed before death. The bottom panel of Table 3-7 shows the mean health percentile of persons in each of the annuity income/financial asset intervals. For example, the mean health percentile of persons with annuity income less than \$10,000 and no financial assets is 24.1. For those with annuity income between \$30,000 and \$40,000 and financial assets between \$25,000 and \$50,000 the median health percentile is 43.3. Thus again the strong relationship between health and wealth is evident.

In short, we find that a large fraction of original single-person households has no housing wealth and very limited financial assets in the last year observed before death. This suggests that the sole source of wealth for many persons is the value of annuity benefits. Most persons receive Social Security benefits (either directly or as a survivor) and about half receive income from a DB pension (again either directly or as a survivor).

4. Compared to What?

It is not clear how we should judge what constitutes a “low” or “sufficient” level of either assets or income. In Table 3-6 we highlighted the distribution of total income by health quintile and age, showing the level of income for persons at the 10th, 25th, 50th, 75th and 90th percentiles with wealth below given levels. At all ages and for all levels of health, total income at the 10th percentile was between \$7,000 and \$10,000. In Table 3-7 we showed the percentage of single-person households with annuity income below levels that were chosen to approximate multiples of the poverty threshold in 2008 (about \$10,000).

We will now provide some rough benchmarks to give context to these income levels just before death. First, we compare total income in the year last observed with total income in 1993 when these persons were first observed in AHEAD. The top panel of Table 4-1 shows median total income by age interval and health quintile in the last year observed before death (which can be any year from 1993 to 2006). These are the same data that were shown as the 50th percentile in Table 3-6. The lower panel shows the total income of these same households in 1993, the first year they were observed in AHEAD. All dollar amounts have been converted to 2008 dollars. On balance, income was slightly lower in the last year before death. It was one percent higher for the 1st health quintile, and then -6 percent for the 2nd quintile, -2 percent for the 3rd, -7 percent for the 4th and -3 percent for the 5th health quintile. The similarity of incomes in 1993 and the last year observed should not be surprising because a large fraction of income is indexed Social Security benefits. These sample members were single in 1993 and single at the time of death and thus did not transition to survivorship benefits. On the other hand, some income is DB pension benefits which are not fully indexed. These data do not suggest that household income

declined in the years just before death. Household assets, in contrast, do show a decline.

Table 4-1. Comparison of total income in last year observed to total income in 1993, original one-person households

health quintile	Age Interval					all
	70-74	75-79	80-84	85-89	90+	
Total income in last year observed						
1	16,353	12,791	14,071	13,219	13,040	13,341

4	22,432	16,904	17,809	14,840	15,814	16,887
5	20,586	21,146	22,342	18,483	19,472	20,586
all	16,952	15,935	15,423	14,097	13,440	14,344
Total income in 1993						
1	16,917	12,406	14,221	13,269	12,864	13,269
2	18,890	21,868	17,586	15,119	14,993	15,947
3	15,031	21,513	18,027	13,690	14,285	16,153
4	22,432	20,532	17,445	16,887	17,375	18,132
5	28,159	28,488	25,296	16,564	19,472	21,146
all	17,621	17,340	16,317	14,097	13,906	14,943

Although it is informative to consider the change in income over the (at most) 13 years of AHEAD (from 1993 to 2006 for persons who died before 2008), we would like to compare resources just before death to resources at a younger age, say prior to “retirement age.” Such a comparison is not easy to make. Nonetheless, we begin by comparing total income of single-persons in the last year observed before death to median earnings of these same persons when they were between ages 57 and 62, based on Social Security earnings records. We first index earnings to 2008 using the SSA Average Index of Monthly Earnings (AIME). We then calculate the median of earnings for ages 57 to 62 excluding years in which earnings were not positive. Approximately half of the original single-person households have matched SSA earnings records. The SSA only records earnings up to the SSA earnings limit which ranged from \$57,600 in 1993 to \$94,200 in 2006. Thus our estimate of pre-retirement earnings may be low for some higher earning workers. More importantly, the Social Security earnings of these original single persons in 1993 may be a very inexact indicator of household resources at the younger age. Many persons may have been married at ages 57 to 62, but were single when first interviewed in 1993. Single women who were previously married may have substantially greater Social Security benefits at older ages than women who never married.

Table 4-2. Comparison of earnings at ages 57 to 62 and total income in last year observed, original one-person households with matched SSA earnings records

health quintile	Age Interval					All
	70-74	75-79	80-84	85-89	90+	
Median of non-zero pre-retirement earnings for ages 57 to 62, AIME indexed						
1	21,468	31,017	29,594	27,711	28,828	28,828
2	32,321	33,539	37,551	31,978	29,465	32,172
3	31,957	42,526	31,318	28,073	28,896	31,318
4	31,029	41,584	26,969	45,607	27,318	34,202
5	51,203	35,990	24,493	38,227	47,373	35,990
All	31,957	35,029	29,981	30,602	29,078	30,651
Total median income in last year observed						
1	16,353	12,791	14,071	13,219	13,040	13,341
2	18,862	18,077	15,877	15,452	13,440	15,012
3	13,353	21,525	15,802	14,253	14,264	15,802
4	22,432	16,904	17,809	14,840	15,814	16,887
5	20,586	21,146	22,342	18,483	19,472	20,586
All	16,952	15,935	15,423	14,097	13,440	14,344

Table 4-2 shows the comparison. Overall median total income in the last year observed was less than half of median earnings at ages 57 to 62. The percentage difference is greatest for those in the poorest health and smallest for those in the best health. Combining all age intervals, LYO income was only 46.3 percent of "pre-retirement" earnings in the first health quintile and 57.2 percent of "pre-retirement" earnings in the fifth health quintile. If these "pre-retirement" earnings are an underestimate of actual pre-retirement earnings, then these "replacement" rates are an overestimate of true replacement rates.

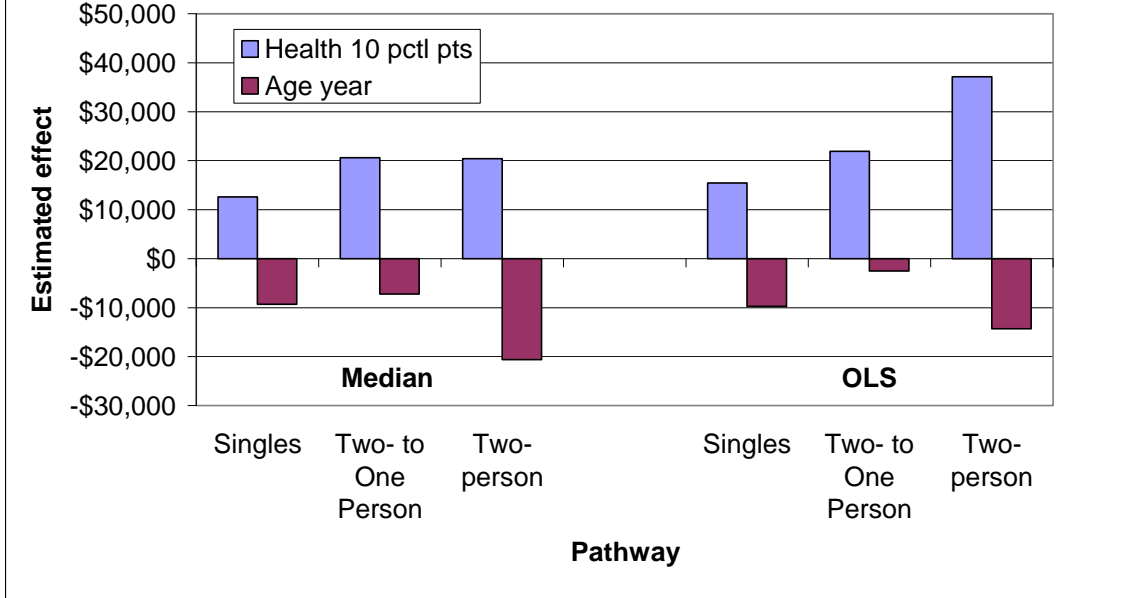

Overall, for the original single-person pathway, we find that a rather large fraction of these single persons have low income judged by poverty thresholds—12.1 percent below the poverty threshold and with no financial assets, 23 percent below twice the poverty line and no financial assets. And the proportion in poverty is much greater for those in poor health than for those in good health. On the other hand, the data show little difference between income just prior to death and income in 1993 when first observed in the AHEAD survey. However, total income in the last year observed is, on average, only about 50 percent of (possibly poorly measured) income in the pre-retirement years. While this difference is hard to evaluate because the two measures are not directly comparable, the implied replacement rate is likely an overestimate of the true replacement rate.

5. The Other Marital Pathway Groups and All Groups Combined

Table 5-1 presents median regression estimates of the effects of age and health on assets in the last year observed. Separate estimates are presented for each of three marital pathway groups. The estimates control for last year observed as a marker for financial market returns that the household experienced since 1993. These estimated age and year effects are the average over all last years observed. Unlike the estimates for single-person households in Table 3-1, these estimated health and age effects are not interacted with LYO but instead show the average effects over all years. The estimates are graphed for all three marital pathway groups in the left side panel of Figure 5-1. The figure shows the effect of a 10 percentile increase in health on total wealth. The estimates range from \$10,000 for single-persons to \$20,000 for the other two pathways. The estimated age effect varies from a decline of \$7,203 per year of age for persons in original two-person households whose spouse is deceased in the last year observed to \$20,619 for persons in original two-person households whose spouse is alive in the last year observed.

Figure 5-1. Estimated median and OLS estimates of the effect of health and age on assets in last year observed, by family pathway

We next consider summary measures of financial resources that focus on the joint distribution of annuity income and liquid financial assets. We first present these results for all family pathways combined. We then compare the results across family pathways. Table 5-2 shows results for all family pathways combined. The table follows the same format as Figure 3-6 for persons in the single household pathway. Among all family pathways, 9.1 percent of persons have annuity income less than \$10,000 (approximately the poverty rate for single persons 65 and older) and no liquid financial assets; 40.0 percent have annuity income less than \$20,000 and financial assets less than \$10,000. Overall, 50.4 percent have no housing wealth. Of those with annuity income less than \$10,000 and no liquid financial assets, 67.0 percent have no housing wealth.

The strong relationship between wealth and health is again observed for persons in all family pathways combined. The median health percentile ranges from 24.3 for persons with annuity income less than \$10,000 to 42.4 percent for those with annuity income between \$30,000 and \$40,000 and financial assets between \$25,000 and \$50,000.

Table 5-2. Selected characteristics of persons in all family pathways, by annuity income and financial assets in the last year observed before death

Financial Assets (\$000s)	Percentage distribution

All	28.0	30.9	32.2	37.2	31.7

Tables 5-3, 5-4, and 5-5 compare results across family pathways. Table 5-3 compares the bivariate cumulative distribution of annuity income and financial assets. The easiest way to compare across pathways is to consider the diagonals in the tables for each pathway. Entries are the proportion of persons below any annuity income/financial asset level. The table shows that more single-person households have low resources than persons in the two-person to one-person pathway (persons in original two-person households whose spouse pre-deceased them), which in turn have lower resources than persons in the two-

person pathway (persons in original two-person households whose spouse is alive at their death). For example the proportion of persons below \$30,000 in annuity income and below \$25,000 in financial assets is 64.5 percent for one-person households, 52.2 percent of two- to one-person households and 38.9 percent for two-person households.

Table 5-3. Percentage distribution of persons by annuity income and financial assets in the last year observed before death, by family pathway

Financial Assets (\$000s)	one-person households				
	Annuity Income (\$000s)				All
	< \$10	< \$20	< \$30	< \$40	
Zero	12.1	23.0	24.2	24.7	24.9
<\$10	23.9	52.0	55.7	56.4	57.0
<\$25	26.3	58.8	64.5	65.7	66.5
<\$50	27.9	65.5	72.8	74.4	75.4

	two-person households				
Zero	6.2	10.1	11.0	11.2	11.6
<\$10	14.8	26.3	30.1	30.8	31.7
<\$25	18.1	33.4	38.9	40.3	41.3
<\$50	21.1	40.5	48.3	50.3	51.6
All	34.2	71.7	90.7	95.3	100.0

Table 5-4 shows the proportion of households with zero housing wealth for each of the three pathways. Again, the diagonal values facilitate the comparison. For example, in the \$20,000 to \$30,000 annuity interval and the \$10,000 to \$25,000 financial asset interval 52.2 percent of one-person households have no housing wealth but only 27.9 percent of one- to two-person households, and just 20 percent of two-person households. Overall, in the last year before death, 57.1 percent of single-person households have no housing wealth and 49.6 percent of persons in two-to one-person households have no housing wealth. Remarkably,

only 20.4 percent of persons who die with a surviving spouse have no home equity.

Table 5-4. Percentage of persons with zero home equity by annuity income and financial assets in the last year observed before death, by family pathway

one-person households

\$25-\$50	17.5	27.4	14.0	10.5	16.9
All	27.0	21.2	18.0	13.1	20.4

Table 5-5 shows the mean health percentile of persons in each of the three pathways. Unlike the very dissimilar proportions of households below annuity income/ financial asset thresholds across family pathways, and the very different proportions with zero housing wealth within annuity income/financial asset intervals, the levels of health within the cells are very similar across family pathways. That is, given similar annuity income and levels of financial assets, the mean health percentile is about the same for persons in each family status pathway. For example, the overall mean health percentile in the three groups is 28.5, 32.3, and 28.5 respectively in the one-person, two- to one-person, and the two-person pathways. For persons in the zero to \$10,000 annuity income and zero housing wealth interval, the mean health percentiles are 24.1, 22.7, and 24.1 respectively.

Table 5-5. Mean health percentile by annuity income and financial assets in the last year observed before death, by family pathway

one-person households					
Financial Asset Interval (\$000s)	Annuity Income Interval (\$000s)				
	\$0-\$10	\$10-\$20	\$20-\$30	\$30-\$40	All

\$25-\$50	26.6	25.3	26.8	43.3	30.2
All	25.1	28.4	29.5	33.4	28.5

Finally, Table 5-6 compares median income in the last year observed with income in 1993. Because of small sample sizes in many cells the table shows data for all health quintiles and for all last years observed combined. For men with matched Social Security records the table also compares median income in 1993 with median earnings for ages 57 to 62. For one-person households and for two-person households total income in the last year observed was, on average, only slightly below income in 1993, for two- to one-person households the decline in income between 1993 and the last year observed was almost 75 percent.

For men with matched Social Security records Table 5-6 shows that for one to one and for two to one person households total income in the last year observed much lower than income when aged 57 to 62—over 68 percent less for one to one households and almost 106 percent less for two to one households. The decline was only 23.2 percent for two to two person households.

Table 5-6. Comparison of median total income in last year observed to median income in 1993 and median earnings when age 57 to 62, all persons, by pathway

Comparison	Pathway		
	One to one	Two to one	Two to two
For all persons			
Total income in 1993	14,943	31,719	34,656
Total income in last year observed	14,344	18,143	33,449
Percent change	-4.2%	-74.8%	-3.6%
For men with matched Social Security records			
Median earnings when age 57 to 62	25,604	40,855	41,584
Medial total income in last year observed	15,213	19,844	33,759
Percent change	-68.3%	-105.9%	-23.2%

6. Summary and Conclusions

We began by summarizing the balance sheets of households in the Health and Retirement Study by five-year age intervals from age 65 to 69 through age 85 and older. These balance sheets show that many households have accumulated considerable wealth, ranging in 2008 from a median of \$214,371 for older single-person households to a median of \$1,015,317 for younger two-person households. Interpretation of these balances is confounded by cohort effects (older generations have lower lifetime earnings than younger generations) and mortality effects (persons in poorer households within a cohort die at younger ages). Thus although these balance sheets present the point-in time wealth of households who survive to a given age they do not reveal the evolution of assets of the same households over time.

To analyze this evolution, we direct attention to the AHEAD households, who were aged 70 and older in 1993 when first observed and age 87 and older in 2008 when last observed. We divide the AHEAD households into three family pathway groups: (1) original one-person households in 1993, (2) persons in two-person household in 1993 with a deceased spouse in the last year observed, and (3) persons in two-person households in 1993 with the spouse alive when last observed. For each of these pathways we describe the evolution of assets from 1993 to the year last observed. We describe the evolution of total wealth and several of its components—financial assets including IRA accounts, housing wealth and housing ownership, Social Security annuity wealth, and DB pension annuity wealth. We find a very strong relationship between health when last observed and the level of assets just before death. Those in poor health have much lower assets than those in good health.

Much of our analysis is restricted to persons who are known to have died. For these persons we are able to calculate wealth in the last year observed before their death. Because waves of the AHEAD are typically spaced two years apart, our last observation for each person is at most two years prior to death. Several general results stand out: 1) Median total wealth was relatively high in the year last observed for each of the three family pathway groups. 2) Wealth in the last year before death is greatest for persons who were in two-person households the longest period of time. For example, the average assets in the last year observed were \$141,606 for persons in one-person households in 1993 whose last year observed before death was 2006, \$252,849 for persons in two-person households in 1993 whose spouse was deceased when last observed in 2006, and \$691,588 for person in two-person households in 1993 whose spouse was alive when last observed in 2006. 3) For total wealth and for each of the asset sub-categories there is a strong correspondence between the level of assets in 1993 and the number of years a person survives after 1993. Persons who lived longer had higher initial assets. 4) For each family pathway group, there is a very strong relationship between health status and wealth in the last year observed. Thus there is a strong association between health and wealth

even among persons who would die within the next two years. 5) Despite the appearance of substantial assets at the median, a substantial fraction of people die with income less than \$10,000 and with no financial assets and with zero housing wealth.

A rather large fraction of the original single-person households have low income judged by the income poverty thresholds. We find that 12.1 percent are below the poverty threshold and have no financial assets, and that 23 percent are below twice the income poverty line and have no financial assets. To put the results in context we first compare the total income in the last year observed to total income in 1993, the first year the AHEAD data were collected. Total income in the last year observed was about 4 percent higher, on average, than total income in 1993. We also compare total median income in the last year observed to median earnings (in 2008 dollars) of the same persons when they were between ages 57 and 62. While the difference is hard to evaluate because the two measures are not clearly comparable, overall median income in the last year observed was approximately 50 percent lower than median earnings of the same persons at ages 57 to 62.

There are also important differences across the pathways. Consider for example the proportion of persons with annuity income less than \$20,000 (approximately twice the poverty level for single persons over age 65) and financial assets less than \$10,000: 52 percent of persons in the single-household pathway fall below these thresholds, but only 36.4 percent of those in the two- to one-person pathway, and only 26.3 percent of those in the two-person pathway. Similarly, consider the proportion of persons with annuity income in the \$10,000 to \$20,000 interval and financial assets less than \$10,000 who have zero housing wealth: of those in the single family pathway 63.3 percent have zero housing wealth, 53.0 percent of those in the two- to one-person pathway, and only 25.9 percent of those in the two-person pathway. A perhaps striking similarity across the pathways is that given income and housing wealth the health status of the persons in the three pathways is very close. The median health percentile of persons with annuity income in the \$10,000 to \$20,000 interval and financial assets less than \$10,000 is 28.2 for persons in the single-household pathway, 23.9 percent for those in the two-to one-person pathway, and 28.2 for persons in the two-person pathway. Finally, the total household income of one to one and two to two households when last observed was only slightly less than income in 1993, while income of two to one households was almost 75 percent lower when last observed than in 1993. And for men with matched Social Security records income when last observed was over 68 percent lower than earning at ages 57 to 62 for one to one households, 106 percent lower for two to one households, but only 23 percent less for two to two households.

The results raise several issues. First, a noticeable fraction of persons die with virtually no financial assets—46.1 percent with less than \$10,000. Based on a replacement rate comparison, many of these may be deemed to have been

well-prepared for retirement, in the sense that their income in their final years was not substantially lower than their income in their late 50s or early 60s. Yet with such low asset levels, they would have little capacity to pay for unanticipated needs such as health or other shocks or to pay for entertainment, travel, or other activities. This raises a question of whether the replacement ratio is a sufficient statistic for the “adequacy” of retirement preparation. In addition, this group relies almost entirely on Social Security benefits for support in retirement. These persons balance on only one leg of the oft touted three-legged stool that is said to provide retirement support—Social Security, pension benefits, and personal saving. If the one leg is judged inadequate it raises the question of how to strengthen the other legs which in turn may, for example, increase interest in the spread of 401(k)-like plans to low-wage workers in firms with high turnover.
