The Impact of Physical Education on Obesity among Elementary School Children
John Cawley, David Frisvold, and Chad Meyerhoefer
NBER Working Paper No. 18341
August 2012
JEL No. H75,I12,I18,I21,K32

ABSTRACT

In response to the dramatic rise in childhood obesity, the Centers for Disease Control (CDC) and other organizations have advocated increasing the time that elementary school children spend in physical education (PE) classes. However, little is known about the effect of PE on child weight. This paper measures that effect by instrumenting for child PE time with state policies, using data from the Early Childhood Longitudinal Study, Kindergarten Cohort (ECLS-K) for 1998-2004. Results from IV models indicate that PE lowers BMI z-score and reduces the probability of obesity among 5th graders (in particular, boys), while the instrument is insufficiently powerful to reliably estimate effects for younger children. This represents some of the first evidence of a causal effect of PE on youth obesity, and thus offers at least some support to the assumptions behind the CDC recommendations. We find no evidence that increased PE time crowds out time in academic courses or has spillovers to achievement test scores.

Introduction

The prevalence of obesity among elementary schoolchildren in the United States nearly quadrupled between 1965 and 2000 (Ogden et al., 2002).² As of 2009-2010, 32.6% of American youths aged 6-11 years are overweight, and 18.0% are obese (Ogden et al., 2012). The U.S. Surgeon General has declared childhood obesity to be an “epidemic” with significant adverse health consequences, including vascular disease and Type 2 diabetes (U.S. D.H.H.S., 2010), that significantly raise health care costs for youth (Trasande and Chatterjee, 2009; Trasande, Liu, Fryer et al., 2009).

The U.S. Surgeon General attributes the rise in childhood obesity, in part, to school cutbacks in physical education (PE) and urges all school systems to mandate daily PE that totals at least 150 minutes per week for elementary schoolchildren (U.S. D.H.H.S., 2010). Other organizations concur, including the American Academy of Pediatrics (AAP), Centers for Disease Control and Prevention (CDC), Institute of Medicine (IOM), and National Association of State Boards of Education (NASBE) (see, e.g., IOM, 2012; AAP, 2006). However, as of 2006, only 3.8% of elementary schools were in compliance with the recommendation of 150 minutes of PE per week (Lee et al., 2007).

Despite the recommendations of the Surgeon General, CDC, and others, there is little evidence of a causal effect of PE on youth obesity. There are several reasons that additional PE may not lower weight or the risk of obesity. First, PE classes may not involve much physical activity. Several studies have used direct observation or accelerometers to measure the amount of time that students spend physically active during PE; they conclude that elementary schoolchildren spend only 9-42% of PE time engaged in moderate to vigorous physical activity

² For children, overweight is defined as a body mass index (BMI) above the historic 85th percentile of the BMI distribution for youth of the same age and gender, and obesity is defined as a BMI above the historic 95th percentile (Barlow et al., 2007). BMI is calculated as weight in kilograms divided by height in meters squared.

(Pate et al., 2011). A second issue is that students may offset any additional physical activity during PE by decreasing physical activity outside of school, with little net impact on physical activity or weight.

This paper contributes to the literature by estimating the causal effect of PE time on the weight of elementary schoolchildren. A large number of studies have reported the correlation of PE with student weight (see Pate et al., 2011, for a review). However, the correlation may be a badly biased estimate of the causal effect for several reasons. First, if enrollment is optional then there may be selection bias; physically fit students may be more likely to enroll. Second, the amount of required PE and enrollment in PE in a school may be correlated with the area's socioeconomic status (SES); e.g. higher-SES schools may require more PE, or may offer more or better PE courses, and may also have more physically fit students because of their higher SES. Alternatively, higher-SES schools may devote more time to academic subjects and less to PE.

A small number of studies estimate the causal effect of PE on youth weight.³ Cawley, Meyerhoefer, and Newhouse (2007) estimate the effect of PE time on the physical activity and weight of high school students, using variation in PE requirements across states as an instrument. Their IV models indicate that PE increases self-reported physical activity but has no detectable effect on the weight of high school students. Datar and Sturm (2004) study the effect of the increase in PE that results from progression from kindergarten to first grade, and find that an additional hour of PE time per week is associated with lower BMI in overweight or obese girls, but results in no change in BMI for healthy weight girls or for boys.

This paper examines the effect of PE on elementary schoolchildren (specifically, those in kindergarten through fifth grade). We analyze data from the Early Childhood Longitudinal

³ There are also studies that involved randomized experiments of innovative PE curricula (for reviews, see Katz, 2009; Brown and Summerbell, 2008), but these studies are not informative about the effect of PE as it currently exists.

Study, Kindergarten Cohort (ECLS-K). Our methods for identifying causal effects are described in the next section.

Methods and Data

The objective of this paper is to measure the causal effect of PE time on the weight of elementary schoolchildren. If PE time was randomly assigned, then one could regress child weight W on time spent in PE (PE), controlling for a vector of relevant observables X :

$$W = \alpha + \beta PE + \delta'X + \varepsilon$$

and interpret the coefficient on PE time, β , as the causal impact of PE on weight.

However, PE time is not randomly assigned. Physically fit students may be more likely to choose PE, and the PE requirements and offerings of individual schools may be correlated with local SES. As a result, the error term ε is likely correlated with the regressor of interest PE , and thus an OLS estimate of the coefficient of interest β is likely biased.

In order to measure the causal impact of PE on weight, one needs to find a natural experiment that creates exogenous variation in PE time without directly affecting student weight (i.e. the instrument should be highly correlated with PE but uncorrelated with ε). The natural experiment that we exploit is variation across states and over time in state requirements for PE for elementary schoolchildren. Using these state policies as instruments, we estimate models of instrumental variables in order to measure the causal effect of PE time on child weight. We cluster standard errors at the state level in all of our models because the instrument varies at the state level.

Data: State PE Policies

Our source for state policies regarding elementary school PE by year is the LexisNexis database of state statutes. These laws were cross-referenced with the Shape of the Nation Reports in 1993, 2001, and 2006, the Trust for America’s Health (TFAH) annual reports that began in 2004, and the State School Health Policy database maintained by the National Association of State Boards of Education; we used these sources to determine when PE was first mandated if historical statutes were unavailable in LexisNexis.⁴

There is significant variation across states in how the legislated mandates are written. For example, some states only require that PE be offered, but do not require that students enroll in it. States also differ in whether they recommend or require a minimum number of minutes per week that students spend in PE; some states specify both a recommended and required number of minutes. The instrument we use is the *required* number of minutes of PE per week.⁵ See Appendix Table 1 for details of the relevant laws by state.

Data: Early Childhood Longitudinal Study, Kindergarten Class of 1998-99 (ECLS-K)

The Early Childhood Longitudinal Study, Kindergarten Class of 1998-99 (ECLS-K) is a nationally representative survey of children entering kindergarten in the 1998-99 school year conducted by the National Center for Educational Statistics of the U.S. Department of Education (Institute of Education Sciences, 2009).⁶ The data were collected on children entering full day and part day kindergarten in either a public or private school. The ECLS-K collected information from children, their parents, their teachers and their schools, using a variety of

⁴ The District of Columbia is excluded from this analysis because its statute wasn’t available on LexisNexis and the Shape of the Nation and TFAH reports were inconsistent.

⁵ The results reported below are robust to including as an additional instrument whether a state has a mandate at all (which may not involve a minimum number of minutes), whether the students are required to take PE (as opposed to schools only being required to offer PE), or the number of recommended minutes.

⁶ The ECLS-K includes respondents from 41 of the 50 states. The states not included are: Arkansas, Idaho, Montana, Nevada, New Hampshire, North Dakota, South Carolina, Vermont, and West Virginia.

methods. Trained assessors interviewed children in schools and measured their weight and height. Parents were surveyed by a trained interviewer over the phone, and teachers and school administrators completed paper and pencil surveys. For more information on the ECLS-K, see the User's Manual (Tourangeau et al., 2009).

Data were collected during the fall and spring of kindergarten (1998-99), fall and spring of first grade (1999-2000), the spring of third grade (2002), the spring of fifth grade (2004), and the spring of eighth grade (2007), but not all of those waves are useful for this analysis. The fall kindergarten wave does not include information on the child's PE participation, so we use that wave only to extract certain time-invariant characteristics of children, such as their race and ethnicity. The wave from the fall of 1st grade included only a 30% sub-sample of the original kindergarten cohort, so this wave is excluded from our analysis. We also exclude the 8th grade wave because it did not record minutes of PE time.

We limit the sample to students attending public school because our identification strategy uses state requirements for PE as instruments, and these requirements apply only to public schools. We also limit the sample to students with non-missing values for state of residence and time spent in PE.

The body weight outcomes of interest (W in the model above) are: BMI z-score, an indicator for whether the child was obese ($BMI \geq 95$ th percentile of the age-gender specific BMI distribution), an indicator for whether the child was either overweight or obese ($BMI \geq 85$ th percentile of the age-gender specific BMI distribution), and the child's weight-for-age z-score. All z-scores and weight classifications are computed using the year 2000 release of the CDC Growth Charts (U.S. D.H.H.S, 2002); the z-scores measure the difference in standard deviation units between a given child's weight and the mean of the historic reference population. All of the

weight variables are calculated using the measured weight and height recorded by the trained assessor during the school visit with the child.

The ECLS-K data also contain various measures of physical activity. In particular, parents are asked the number of days per week that their children exercise vigorously for 20 minutes or more, whether they are more or less active than other children of the same age, and whether they received regular exercise through various activities during the past 12 months. Information on relative physical activity was collected for structured activities at school, such as team sports, activities during the child's free time, and aerobic activities during which the child sweats and experiences increased heart rate. We created indicator variables for whether parents perceived their children to be more physically active than others for each of these three categories. We also created indicator variables for whether parents reported that their children received regular exercise during the past 12 months through the following activities: group sports, individual sports, recreational sports, general exercise, dance, karate, playground activities, and other sports.

The ECLS-K also asks parents how much time their children spend watching TV on school days as well as weekend days, which we use as a proxy for sedentary activities. We combined reported levels of TV watching on weekdays and weekend days to create a measure of total TV minutes per week.

Because of the age of the children, they were not considered to be reliable sources of information on their number of minutes of PE per week, so the ECLS-K collected the information from the best informed party: the student's teacher. Teachers reported the number of days per week that the student had PE class (the options are: never, less than once, 1-2 times, 3-4 time, or every day) and the minutes per day (the options are: 0, 1-15, 16-30, 31-60, or more

than 60). We created one measure of days of PE instruction using the midpoint of the intervals and a second measure using the upper limit of the intervals. Likewise, we computed two measures of PE minutes per day; one using the midpoint of the intervals, using 75 minutes for the highest category, and one using the upper limit of the intervals, using 90 minutes for the highest category. We then generated three measures of how many minutes per week each child spent in PE by multiplying the following variables together: (1) midpoint for PE days/wk and the midpoint for PE minutes/day; (2) midpoint for PE days/wk and the maximum for PE minutes/day, and (3) maximum for PE days/wk and the maximum for PE minutes/day. All of the measures generated similar results in our empirical models, so we report the measure (2) because we think that daily instructional times are much more likely to correspond to the upper interval numbers, while the number of days per week of PE is likely to be uniformly distributed within the reported interval. Using the maximum values of PE minutes per day is conservative (i.e. we are potentially assuming children spent more time in PE than they actually did, so our impacts of PE times on outcomes should be attenuated).

In the waves for kindergarten through third grade, one teacher was asked to provide this information. However, in the fifth grade wave two teachers (reading and math) were asked to provide this information; in this case we use the average response across the two teachers.⁷

Because PE time is reported by teachers, and is furthermore reported in categories, there is likely measurement error in PE time that, without adjustment, biases estimates of the coefficient on PE time. An advantage of the method of IV is that, in addition to addressing the endogeneity of PE time, it reduces the bias from measurement error in the endogenous regressor; see Bound et al. (2002).

⁷ Both teachers give similar estimates of time the child spends in PE; the mean (standard deviation) of reported weekly PE time is 100 (70) by the reading teacher and 101 (70) by the math/science teacher.

The set of control variables (X in the model above) includes: child age, gender, race/ethnicity (White, Black, Hispanic, Other), birth weight, population density of residence (Urban Suburban, Rural), family income, family size, and the years of education of the most educated person in the family. Our models also include controls for grade, public school type (Charter school, Magnet school, Special education school, Bureau of Indian Affairs school, or Early childhood center), and the percentage of students at the school eligible for a free or reduced price lunch.

Policy endogeneity is a concern whenever policies are used as instruments (see, e.g., Cawley and Ruhm, 2012). That is, wealthier or more progressive states may pass higher standards in education, as well as have populations in better health for a variety of reasons. To address this possibility, we control for state characteristics related to income, education and health; specifically: real per capita income, the percentage of adults in the state with a bachelor's degree or higher, the state percentage of overweight and obese girls and boys, the state percentage of overweight adults, the average public school pupil-to-teacher ratio, real total state tax revenues per student, and real state instructional expenditures per teacher. Per capita income and adult education were obtained from the U.S. Census Bureau; the percentage of obese and overweight children was obtained from the Centers for Disease Control and Prevention; and the other variables were obtained from the U.S. Department of Education. Additionally, from the U.S. Department of Agriculture we obtained state participation per student in the National School Lunch Program (NSLP), School Breakfast Program (SBP), and Summer Food Services Program (SFSP). We use these measures to control for poverty, the quality of school meals, and access to food assistance.

Empirical Results

Summary Statistics and Descriptives

Table 1 lists summary statistics for the ECLS-K variables used in the analysis. The average number of minutes per week spent in PE rises from 76 minutes in kindergarten to 87 minutes in 1st grade, 91 minutes in 3rd grade, and 104 minutes in 5th grade. During elementary school, the prevalence of overweight rises from 26.1% in kindergarten to 40.5% in fifth grade, and over the same period the prevalence of obesity roughly doubles from 11.8% to 22.4%.

Appendix Table 1 describes the PE requirements for elementary schools that prevailed in each state during each wave of the ECLS-K. Table 2 shows the change over time in state PE mandates. Between the ECLS kindergarten wave (1999) and the 5th grade wave (2004), the number of states that did *not* mandate PE for elementary schoolchildren fell from 21 to 13, and the number of states that required a specific number of minutes per week of PE for elementary schoolchildren rose from 2 to 11. The increase in the number of states with PE mandates between the kindergarten wave in 1999 and the first grade wave in 2000 is due to the fact that many states require PE of 1st graders but not kindergarteners (i.e. it is due to grade progression; no states changed PE requirements for first graders between 1999 and 2000). In contrast, the increase in the number of states with PE mandates between the first grade wave in 2000 and the fifth grade wave in 2004 is due to states enacting new PE mandates.

Figure 1 depicts the requirements as of 2004, the timing of the 5th grade wave of the ECLS-K. In 2004, eleven states mandated a specific number of minutes of PE per week, and these states ranged from relatively liberal and high-SES states such as California, New York, and New Jersey, to relatively conservative and low-SES states such as Alabama, Mississippi, and

Arkansas. In addition, 26 states mandated PE without specifying a minimum number of minutes, and 13 states did not mandate PE for elementary schoolchildren.

Table 3 lists the percent of ECLS-K students who were subject to a mandated number of minutes in PE. In kindergarten, only 6% of the sample was subject to a PE mandate with a minimum required number of minutes. That jumped to 26% in 1st grade, remained roughly constant at 27% in 3rd grade, and jumped to 38% in 5th grade.

The impact of state policies on PE time (1st stage of IV)

The first stage of our IV method uses the state mandated number of PE minutes per week as an instrument for the number of minutes per week the child spends in PE. A reasonable question to ask is whether schools comply with these state mandates. For example, a study by the New York State government found that students in grades K through 3 received only 72% of the PE class time, and students in grades 4 and 5 received only 77% of the PE class time, that New York State required (Office of the New York State Comptroller, 2008). In general, the Institute of Medicine (IOM) has concluded that there is insufficient enforcement of state PE standards (IOM, 2006).

We calculated estimates of student compliance. Across all waves of the ECLS-K, only 34% of students in states with a mandated number of minutes were in PE for the required number of minutes. Compliance varies with grade and year, from 17% in kindergarten to 31% in 1st and 3rd grades to 45% in 5th grade. Less than perfect compliance by schools reduces the power of state mandates to affect individual student PE time.

The first stage of our IV model is reported in Table 4. The first stage is calculated for all waves pooled (column 1) as well as for each wave separately (subsequent columns). The results

of the first column indicate that the instrument (number of required minutes) is a significant predictor of individual student PE time in the pooled sample. However, the subsequent columns reveal that this correlation is driven solely by the 5th grade wave. Not only is the instrument only statistically significant in the 5th grade wave, but the point estimate of the coefficient is several times larger in that wave than any other. Moreover, only in the 5th grade wave does the F statistic associated with the instrument exceed 10, the conventional minimum standard for the power of a continuous instrument (Stock, Wright, and Yogo, 2002). Specifically, the F statistic in the 5th grade wave is 21.7.

The point estimate of the coefficient on the instrument indicates that a state mandate of an additional 100 minutes of PE per week translates into an actual increase in PE time of only 13 minutes for kindergarteners, 2 minutes for first-graders, 4 minutes for third-graders, and 40 minutes for 5th graders.

The statistical significance of the instrument in the 5th grade wave, as opposed to any other, is driven by increases in state-mandated PE time between 2002 (the 3rd grade wave) and 2004 (the 5th grade wave). The average number of minutes per week spent in PE in states with a minute requirement was 89 in 2002, but that rose to 127 in 2004. This increase is the result of both new states adopting minutes requirements (that were substantial) between 2002 and 2004, and increases in PE time among states that had enacted minutes requirements earlier (in particular, those that adopted them prior to 2000).

The effect of PE time on child weight (2nd stage of IV)

Table 5 presents results of the second stage of IV, and (for the sake of comparison), results from OLS regressions. We continue to present results for the pooled sample, as well as

for each wave individually, and we focus in particular on the results for the 5th grade wave, given that the instrument is sufficiently powerful only in that wave.

In the 5th grade wave, the IV coefficient on PE minutes is negative and statistically significant at the 1% level. The point estimate implies that an additional 50 minutes per week in PE (roughly what is needed to bring the mean up to the minimum amount recommended by the AAP and CDC) would lower BMI z-score by 8 percent of a standard deviation, or 12 percent of the mean BMI z-score in the sample. The negative sign of the IV coefficient in the 5th grade wave (final column) is consistent with the sign of the corresponding OLS coefficient (second-to-last column), although the IV point estimate is greater in absolute magnitude than that from OLS; this difference may be due to IV correcting for measurement error in PE time, or may be a result of the OLS estimate being biased by selection or omitted variables.

We report the results of IV models for other weight outcomes in Table 6. These estimates are based on the 5th grade wave only, because it is only in that wave that the instrument is sufficiently powerful. The IV models indicate that PE reduces the probability of overweight, obesity, and the weight z-score; in each case the IV coefficient is statistically significant at the 1% level. The point estimate implies that an additional 50 minutes per week in PE (roughly enough to raise the mean to the amount recommended by the AAP and CDC) reduces the probability of youth obesity by 4 percentage points, which is 18 percent of the baseline prevalence.

In summary, for each of the four measures of weight (BMI z-score, weight z-score, overweight, obese), the IV model consistently finds that PE time reduces child weight.

We also investigate mechanisms, and the possibility of offsetting behavior, in Table 7. There, we report the results of IV models of PE time on various measures of overall physical

activity, as reported by the parent. The IV results, presented in Table 2, suggest that additional PE leads to greater overall participation in structured physical activity and more physical activity overall. There may also be some crowd-out, however, as the IV models also indicate that additional PE time reduces the probability of participation in dance and in playground activities. For the remaining activities (including days per week of vigorous exercise, participation in other specific physical activities and TV minutes per week) we cannot reject the null hypothesis of no effect of PE.

Falsification Tests:

When using policies as instruments, one must be wary of policy endogeneity (e.g. Cawley and Ruhm, 2012). Because we are concerned that states which enact or raise PE minute mandates may differ in important ways from those which do not, we control in our models for a wide variety of state characteristics relating to income, health, and education. Consistent with a lack of policy endogeneity, no state characteristics are statistically significant at the 5 percent level (and only one of 12 is significant at the 10 percent level) in regressions of the required number of PE minutes on the set of state characteristics in 2004, which is the year of 5th grade wave of the ECLS-K. Likewise, no state characteristics in 2002 are significantly associated with the change in required number of PE minutes between 2002 and 2004. However, it is possible that even controlling for these observed characteristics, there may remain a problem of policy endogeneity that would imply our instrument is invalid and the IV estimates are biased.

To investigate this possibility we conduct several falsification tests. Specifically, we estimate our IV model for the following weight-related outcomes: birth weight, BMI in the fall semester of kindergarten, and height z-score. These are not plausibly affected by PE in

elementary school, so a correlation with PE time would imply that our instrument is invalid. Results of the falsification test are shown in Table 8. In no case does the IV model suggest that PE time affects any of these three outcomes; none of the IV coefficients comes close to being statistically significant.⁸ These results should be interpreted cautiously; a failure to reject the null hypothesis does not prove the null. However, the falsification tests yield no evidence of policy endogeneity and are consistent with our identifying assumptions.

Extension: Crowd-Out of Academic Class Time, Spillovers to Academic Achievement

As an extension, we test whether there are unintended consequences of mandating additional PE time, specifically whether a higher number of mandated minutes crowds out time in academic classes, or has spillover effects on academic test scores.

To test for crowd-out, we estimate the same IV model as earlier, except that the dependent variable is the number of minutes in specific academic classes, such as reading, writing, math, social studies, science, and foreign languages. We also examine time spent in enrichment classes, such as music and art, as well as in lunch and recess.⁹

The results of these models are presented in Table 9. The IV results, in the center column, indicate that increased PE time does not lead to a significant crowd-out of time in any academic class. The only significant decrease in class time is for music; a one-minute increase in PE time is associated with a 0.2 minute decrease in music class. Instead of schools cutting academic classes when PE mandates are increased, they seem to increase the length of the school

⁸ Consistent with the estimates in Table 8, the main results are robust to controlling for fall kindergarten BMI z-score.

⁹ As described in the appendix, of the 11 states with a minimum required number of minutes for 5th grade in 2004, only Texas requires physical activity more generally, which may include recess in addition to PE. The results in Table 9 show that state PE requirements and time in PE are not associated with a change in time spent in recess. Additionally, the main results are robust to excluding students in Texas from the sample. Thus, the results throughout the paper reflect the impact of PE, as opposed to physical activity more generally.

day. The first row of Table 9 shows that a one-minute increase in mandated PE time is associated with a 1.6 minute increase in the length of the school day.

Based on these findings, one would not expect raising PE mandates to lower scores on achievement tests. On the contrary, some have argued that PE may improve achievement test scores, as physical activity may enhance cognitive functioning (e.g. Tomporowski, 2003). However, the results of IV models of the impact of PE on achievement test scores (presented in Table 10) consistently yield no evidence of spillover effects of PE on achievement test scores for reading, math, or science.

Subgroup Analyses: Differences by Gender

We also investigate whether the relationship between additional PE time and weight varies by gender. IV models were estimated separately by gender, and results are presented in Table 11. The F statistics for both boys and girls exceed the conventional minimum threshold of 10 (18.2 for girls, 25.8 for boys), and the first-stage coefficients are similar for both boys and girls (0.401 for girls, 0.395 for boys).

The IV results in Table 11 indicate that increased PE time reduces weight only for boys; the reduction is statistically significant for all three measures of weight (BMI z-score, overweight, and obese). In the IV models, an additional 50 minutes of PE time reduces BMI z-score by .15 of a standard deviation, and reduces the probability of overweight and the probability of obesity by 6 percentage points. Although the probit models indicate that girls who spend more time in PE are less likely to be overweight and obese, the IV coefficients are not statistically significant, and thus it is not possible to reject the null hypothesis that additional PE time has no effect on weight for elementary school girls.

Discussion

This paper estimates IV models of the effect of PE time on child obesity. The IV models address both endogeneity of PE time and measurement error in PE time. The results of the IV models indicate that an additional 50 minutes per week of PE time (enough to raise the mean to the amount recommended by the AAP and CDC) lowers BMI z-score by 12 percent of the mean, and reduces the probability of obesity by 4 percentage points.

Our results are limited to 5th graders (i.e. the 2004 wave of ECLS-K), because it was around that time that a substantial amount of variation in the relevant policies occurred. First, as noted above, there was an increase in the number of states adopting PE requirements with a minimum number of minutes. Second, the 5th grade wave of the ECLS-K, which is the 2003-2004 school year, was the first wave under which the formal school accountability policies enacted under No Child Left Behind (NCLB) would have been effective. In response to accountability pressures, schools may decrease the amount of time in PE to offer more time in the tested subjects (Pate et al., 2006). Consistent with this possibility, Anderson, Butcher, and Schanzenbach (2012) and Yin (2012) find that accountability policies increase childhood obesity. Thus, state PE requirements would be more effective in increasing time spent in PE in the 2004 wave of the ECLS-K because these requirements limited schools' ability to strategically respond to the accountability pressures of NCLB.

Our subgroup analyses indicate that the effects of PE on weight in the 5th grade wave are concentrated among boys. This may be due to factors on the supply side (boys may voluntarily be more physically active during PE) or factors on the demand side (PE teachers may structure different activities for boys and girls in PE, or demand more of boys in the same activities).

Better understanding gender differences in the impact (and curriculum) of PE is clearly a priority for future research.

Although we find beneficial effects of PE on weight for only certain grades (waves), and only for boys, these results offer some of the first confirmation of an important assumption behind the calls by the CDC, AAP, IOM, and other groups for school districts to increase required PE time for elementary schoolchildren in order to prevent obesity.

More generally, this study represents a response to the call of the IOM to evaluate the effects of policies and programs and thereby increase the knowledge base regarding what works to prevent childhood obesity (IOM, 2006). This information is valuable because childhood obesity is associated with impaired health, social stigma, and elevated health care costs (IOM, 2005).

What policymakers would most like to know is the Average Treatment Effect (ATE) of PE, but what is estimated by IV models is the Local Average Treatment Effect (LATE). The LATE may differ from the ATE if state mandates increase PE only in certain types of schools. For example, high-SES schools may already satisfy the new mandate (because they have more of everything) or may be less likely to already satisfy the new mandate (if they are focused on academics to the exclusion of PE). In addition, the instrument was sufficiently powerful only in 2004 (the 5th grade wave of ECLS-K) and if the treatment effect is heterogeneous with age then the results for 5th graders may not generalize to schoolchildren of other ages. In related work, Cawley, Meyerhoefer, and Newhouse (2007) used PE unit credit requirements (i.e. mandates in the form of semester courses rather than minutes per week) as instruments for PE time during high school, and found no detectable impact of additional PE on high school students' BMI or

the probability of obesity.¹⁰ As with gender, it is clearly a priority for future research to better understand how the curriculum of PE, and the effect of PE, vary by grade and age.

Our findings confirm earlier studies that found weak compliance by schools with state PE mandates (e.g. IOM, 2012; IOM, 2006). Our estimates indicate that an increase of 100 minutes in the state mandate translates into only 40 additional minutes of PE class time among 5th graders. To some extent, the less than one-to-one correspondence may be driven by some schools already satisfying the mandate, but we consistently find that only a minority of students are compliant with state mandates. This suggests that states wishing to increase youth physical activity may wish to enforce existing PE mandates, in addition to raising the number of mandated minutes (IOM, 2012).

The results of this paper indicate that increased PE leads to greater overall participation by elementary schoolchildren in structured physical activity and more physical activity overall. Beyond its impact on youth weight, this is important because increased physical activity by youths is associated with cardiovascular benefits such as a reduction in low-density lipoproteins (bad cholesterol) and the prevention or delay of hypertension; musculoskeletal benefits such as increased bone-mineral density and increased strength and endurance; mental and emotional benefits such as reduced stress and anxiety; and prevention of chronic disease (IOM, 2005).

This paper finds no evidence that additional PE time crowds out academic subjects. We also find no evidence that PE has any spillover effects onto achievement test scores. These findings are consistent with those of Dills et al. (2011).

¹⁰ Cawley, Meyerhoefer, and Newhouse (2007) used PE credit units, rather than minutes per week, as an instrument, because the former are the way in which state requirements for high school students are expressed: in terms of semesters of coursework needed to graduate. This paper uses minutes per week as an instrument because state requirements for elementary school students are expressed in terms of minutes per week rather than credit units for graduation. That is, in each paper the instrument matches the way state laws express requirements for the grades involved.

Concerned by the possibility of policy endogeneity that might bias the IV estimates, we control in our models for a host of state characteristics related to income, education, and health, including per capita income, education levels, prevalence of obesity, pupil-to-teacher ratio, tax revenues per student, expenditures per teacher, and participation in subsidized school meal programs. Moreover, we conduct several falsification tests and find no evidence that increased PE time affects weight-related variables that it shouldn't, specifically: birth weight, BMI z-score in the fall of kindergarten, and height z-score. In summary, we find no evidence that policy endogeneity biases the IV results, but caution that evidence from falsification tests is only suggestive, not definitive.

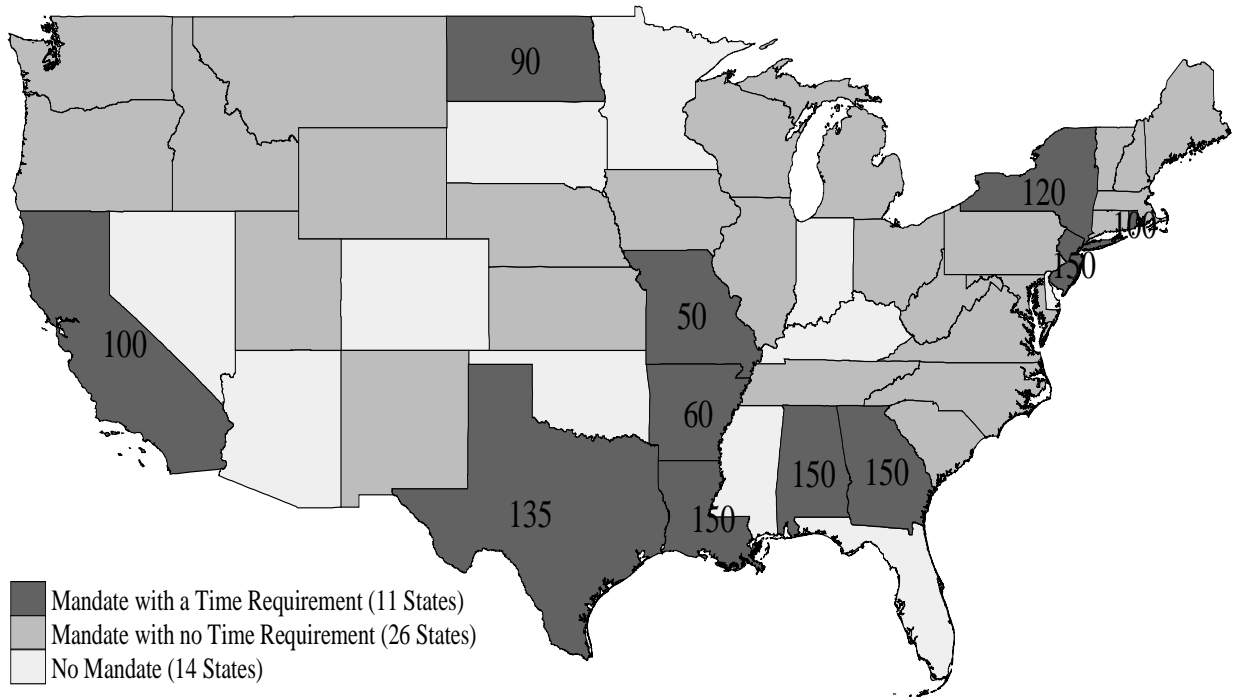

A limitation of this paper is that the weight-related outcomes we examine (BMI z-score, overweight, obesity) are based on body mass index, which is a flawed measure of fatness because it ignores the distinction between fat and muscle (Burkhauser and Cawley, 2008). Physical activity that builds muscle and burns fat will have an ambiguous impact on BMI. An ideal dataset would include measures of both fat mass and lean mass (which can be calculated using technology such as Bioelectrical Impedance Analysis or Dual X-Ray Absorptiometry), allowing researchers to measure the effect of PE on muscle and fat. However, this limitation is less relevant for elementary school students, whose PE involves less muscle-building exercise and who are less prone than adolescents to adding muscle mass.

Observations	43430	14430	11590	8870	8550

Notes: Standard deviations in parentheses. Sample sizes rounded to the nearest 10 in order to comply with Department of Education non-disclosure requirements.

Data: ECLS-K

**Table 2:
Number of States with PE Requirements by Year and Grade Level**

	Kindergarten 1999	1st grade wave 2000	3rd grade wave 2002	5th grade wave 2004
States without a Mandate	21	15	13	13
States with a Mandate but no Minutes Requirement	27	29	28	26
States with a Mandate and a Minutes Requirement	2	6	9	11

Notes: State mandates are based on the year and the applicable grade of students in the ECLS-K data, so that the decrease in states without a mandate from 1999 to 2000 is due to state mandates that do not apply to kindergarten students. Figure 1 shows the geographic distribution of state laws in 2004. Additional details about the state laws are included in the appendix.

Sources: See Appendix.

**Table 3:
Percent of Students in the Sample Subject to a Mandate in each Year and Survey Wave**

	All Waves 1999-2004	Kindergarten 1999	1st grade wave 2000	3rd grade wave 2002	5th grade wave 2004
Students subject to a Mandate	0.72 (0.45) <i>43430</i>	0.59 (0.49) <i>14430</i>	0.77 (0.42) <i>11590</i>	0.79 (0.41) <i>8870</i>	0.78 (0.41) <i>8550</i>
Students subject to a Mandate with a Minutes Requirement	0.22 (0.41) <i>43430</i>	0.06 (0.25) <i>14430</i>	0.26 (0.44) <i>11590</i>	0.27 (0.44) <i>8870</i>	0.38 (0.48) <i>8550</i>
Average Minutes Requirement among Students subject to a Mandate with a Minutes Requirement	117.70 (26.75) <i>9510</i>	132.02 (14.71) <i>930</i>	118.87 (22.33) <i>2990</i>	110.70 (30.43) <i>2380</i>	117.65 (28.45) <i>3220</i>

Notes: Standard deviations in parentheses. The numbers of observations (in italics) are rounded to the nearest 10 to comply with non-disclosure requirements.

Data: Early Childhood Longitudinal Study, Kindergarten Cohort

Table 4:
First Stage:
Relationship between State Mandates and Time in PE

	All Waves 1999-2004	Kinder- garten 1999	1st grade wave 2000	3rd grade wave 2002	5th grade wave 2004
Number of Required Minutes	0.1309** (0.0523)	0.1256 (0.0823)	0.0157 (0.0863)	0.0420 (0.0881)	0.3977*** (0.0853)
F statistic	6.267	2.328	0.0333	0.227	21.74
Observations	42910	14210	11480	8770	8470

Notes: Heteroskedasticity-robust standard errors that allow for clustering within states in parentheses. The numbers of observations are rounded to the nearest 10 to comply with non-disclosure requirements. The F statistic corresponds to the hypothesis test that the coefficient for the number of required PE minutes is equal to zero. The individual and household characteristics included, but not shown, are: sex, age, grade, race/ethnicity (black, Hispanic, and other race/ethnicity, with white excluded), family income, family size, parent's education, parent's education is missing, birth weight, birth weight is missing, population density (urban or rural, with suburban excluded), and population density is missing. The school characteristics included, but not shown, are: the percent of free and reduced-price eligible students and the type of school (magnet, charter, special education, and early education, with regular excluded). The state characteristics included, but not shown, are: real per capita income, the percent of adults with a bachelor's degree, the prevalence of childhood obesity among boys and girls, the average pupil/teacher ratio in public schools, real total state tax revenue per student, real state instructional expenditures per student, and the percent of students participating in the National School Lunch Program, School Breakfast Program, and Summer Food Service Program.

Data: Early Childhood Longitudinal Study, Kindergarten Cohort

**Appendix Table:
State Physical Education Requirements for Grades K-8 in 1999 through 2007**

State	Mandate	Minutes	Year Enacted	Notes
Alabama	Y	150	1940	Schools are required to offer PE. Beginning in 2003-2004, all students in grades K-8 are required to participate in daily PE, with no exceptions or substitutions, and at least 30 minutes each day (150 minutes per week) are required for students in grades K-6. At least 50 minutes each day are recommended by the Department of Education for students in grades 7-8. Applicable statutes: Code of Alabama § 16-40-1 and Code of Alabama, 1975, §16-35-4.
Alaska	N			
Arizona	N			Since 1978, students have been required to demonstrate a minimum level of competency in PE (State Board of Education Administrative Code R7-2-301). There is no requirement to participate in PE or for schools to offer PE.
Arkansas	Y	60	2002	Students in grades K-8 have been required to participate in PE at least 3 times each week for at least 20 minutes beginning in 2001-2002. Applicable statute: 2001 Ark. ALS 1748.
California	Y	100	1977	Beginning in 1977, students in grades 1-6 have been required to participate in at least 200 minutes each 10 schooldays of PE and students in grades 7-8 must participate in at least 400 minutes each 10 schooldays. Recess may not be included in these requirements. Applicable statutes: Cal Ed Code § 51210, Cal Ed Code § 51222.
Colorado	N			
Connecticut	Y	0	1978	Schools are required to offer PE. Beginning in 2004-2005, students in grades K-5 are required to participate in daily PE. Applicable statutes: Conn. Gen. Stat. § 10-16b, Conn. Gen. Stat. § 10-221o.
Delaware	Y	0	2006	Since 2005-2006, students in grades 1-8 have been required to participate in PE. Applicable statute: CDR 14-500, 14 Del. C. §122(d).
Florida	N			Florida did not require PE until 2007-2008. By December 2004, all school districts were required to develop a PE program that encourages students to participate in PE. For 2006-2007, districts were encouraged to provide 150 minutes per week for students in grades K-5 and 225 minutes per week for students in grades 6-8. Applicable statutes: 2004 Fl. ALS 255, 2006 Fl. ALS 301.
Georgia	Y	150	1990	Schools are required to provide a minimum of 90 hours per year of PE for students in grades K-5. Schools are required to make PE available to students in grades 6-8. Applicable statutes: Ga. Comp. R. & Regs. r. 160-4-2-.12, O.C.G.A. § 20-2-142.
Hawaii	N			PE requirements will not be effective in Hawaii until 2010-2011. Beginning in 2005-2006, the Hawaii Department of Education recommends 45 minutes of PE per week for students in grades K-3, 55 minutes of PE per week for students in grades 4-5, and 200 minutes of PE per week for students in grades 6-8. Source: State of Hawaii Wellness Guidelines.
Idaho	Y	0	1963	Schools are required to offer PE. Applicable statute: Idaho

				Code § 33-1605
Illinois	Y	daily	1996	Students in all grades are required to participate in daily PE. Recess may contribute to the daily PE requirement for students in all grades if recess is supervised by a certified teacher. Applicable statute: 105 ILCS 5/27-6.
Indiana	Y	0	2006	Beginning in 2005-2006, schools are required to offer PE. Beginning in 2006-2007, schools are required to provide daily PE for elementary school students, which may include recess. Indiana State Board of Education recommends that students in grades 1-3 participate in 105 minutes per week of PE, students in grades 4-6 participate in 75 minutes per week, and students in grades 6-8, when grade 6 is included in a middle school, participate in 100 minutes per week. Applicable statutes: Burns Ind. Code Ann. § 20-30-5-7, Burns Ind. Code Ann. § 20-30-5-7.5, 511 IAC 6.1-5-2.5
Iowa	Y	0	1986	Physical education is required to be taught in grades 1-8. Applicable statute: Iowa Code § 256.11.
Kansas	Y	0	1993	Schools are required to offer PE in elementary and secondary school to receive accreditation. Beginning in 2005-2006, the state Board of Education recommends at least 100 minutes per week. The available state statutes date back only to 2005. According to the Shape of the Nation and Trust for America's Health reports, the requirement dates back to at least 1993. Applicable statute: K.A.R. § 91-31-32
Kentucky	Y	0	2007	Beginning in 2006-2007, students in grades K-8 are required to participate in PE as part of the state curriculum. Applicable statute: 704 KAR 3:303.
Louisiana	Y	150	1980	Schools are required to provide PE for at least 30 minutes each day to students in grades 1-6. Applicable statute: 2004 La. ALS 734, La. R.S. 17:17.1, State Bulletins 102 and 103.
Maine	Y	0	1983	Schools are required to offer PE. Applicable statute: 2001 Me. ALS 454.
Maryland	Y	0	1996	Schools are required to offer PE. Applicable statute: Md. EDUCATION Code Ann. § 7-409.
Massachusetts	Y	0	1962	Schools are required to offer PE. Applicable statute: ALM GL ch. 71, § 1.
Michigan	Y	0	1977	Schools are required to offer PE. Beginning in 2003-2004, the state Board of Education recommends that all schools offer PE for 150 minutes per week for grades K-5 and for 225 minutes per week for grades 6-8. Applicable statute: MCLS § 380.1502.
Minnesota	Y	0	2006	Students are required to participate in PE beginning in 2005-2006 in grades 1-10. Applicable statutes: 2005 Minn. ALS 5, Statute 120A-22
Mississippi	N			Students in grades K-8 are required to participate in PE for 150 minutes per week beginning in 2007-2008. Between 2002-2003 and 2006-2007, the legislature recommends that students in grades K-8 participate in PE for 150 minutes per week. Applicable statutes: Miss. Code Ann. § 37-13-134, 2002 Miss. ALS 585.
Missouri	Y	50	1995	Schools are required to provide PE to all students in all public schools at least as far back as 1995. Beginning in 2001-2002, students in grades K-5 are required to participate in 50 minutes per week of PE and students in grades 6-8 are required to receive 3000 hours of instruction in PE per year. Applicable statutes: § 161.102 R.S.Mo. and Missouri School Improvement Program.
Montana	Y	0	1998	Schools are required to offer PE. Applicable statute: MONT. ADMIN. R. 10.54.2501.

Nebraska	Y	0		Schools are required to offer PE in elementary and middle schools. The initial date of this requirement is unknown. Applicable statute: Nebraska Admin. Code Title 92, Ch. 10-004.03A9.
Nevada	N			There is no mandate that students participate in PE, but, beginning in 1999-2000, PE “must be taught as applicable for grade levels and to the extent practicable in all public schools.” Applicable statute: Nev. Rev. Stat. Ann. § 389.018.
New Hampshire	Y	0	1975	PE is required to be taught to students in all grades beginning in 1975 or possibly earlier. Beginning in 2004-2005, the school boards of each school district were required to adopt a policy recommending daily PE. Applicable statute: RSA 189:10, RSA 189:11-a.
New Jersey	Y	150	1967	Students are required to take courses in PE and health in grades 1-12 for a combination of 150 minutes per week. Local school districts determine the percentage of the 150 minutes that is allocated to PE. Applicable statute: N.J. Stat. § 18A:35-7, N.J. Stat. § 18A:35-8.
New Mexico	Y	0	1967	Schools are required to provide PE in grades 1-8. Applicable statute: N.M. Stat. Ann. § 22-13-1.
New York	Y	120	1983	Beginning in 1982-1983, students in grades K-3 must participate in PE daily and students in grades 4-6 must participate in PE at least 3 times per week. Students in grades K-6 must participate in at least 120 minutes per week. Schools are required to offer PE to students in grades 7-8 at least 3 times per week in one semester and 2 times per week in the other semester. Applicable statute: 8 NYCRR § 135.4.
North Carolina	Y	0		Students in grades K-8 are required to participate in PE. The recommended minimum amount of PE is 150 minutes per week for students in grades K-5 and 225 minutes per week for students in grades 6-8. The initial date of this requirement is unknown. Applicable statutes: Policy ID Number: GCS-S-000, N.C. Gen. Stat. § 115C-12.
North Dakota	Y	90	2001	Students in grades K-8 are required to participate in PE. PE is required for students in grades 7-8 for 80 minutes per week and for 90 minutes per week for students in grades 1-6. Applicable statutes: N.D. Cent. Code, § 15.1-21-01, Administrative Rules 67-19-01-34 and 67-19-01-35.
Ohio	Y	0	1993	Schools are required to offer PE for students in all grades. Applicable statute: OAC Ann. 3301-35-04.
Oklahoma	N			Beginning in 2006-2007, schools are required to provide PE for elementary school students for at least 60 minutes per week. This requirement does not apply to middle school students and PE was not mandated prior to 2006-2007. Applicable statute: 70 Okl. St. § 11-103.9.
Oregon	Y	0	1998	Beginning in 1997-1998, schools are required to offer PE to students in all grades. Applicable statute: Or. Admin. R. 581-022-1210.
Pennsylvania	Y	0	1999	PE is required to be taught to students in all grades. Applicable statute: 22 Pa. Code § 4.27.
Rhode Island	Y	100	1956	Students are required to participate in PE for at least 20 minutes each day in grades 1-12. Recess cannot count towards the PE requirements. Applicable statute: Rules and Regulations of School Health Programs.
South Carolina	Y	0	1976	Students are required to participate in PE. Beginning in 2006-2007, students in K-5 must participate in physical activity for at

South Dakota	N			least 150 minutes per week of which 60 minutes must be PE. Applicable statute: S.C. Code Ann. § 59-10-10.
Tennessee	Y	90	1975	Schools are required to offer PE to students in grades K-8. Beginning in 2006-2007, at least 90 minutes of physical activity must be provided throughout the day for students in grades K-8. Applicable statute: Tenn. Comp. R. & Regs. R. 0520-01-03-.05. Schools must offer PE to students in grades K-5 since at least 1993. Beginning in 2002-2003, students in grades K-6 must participate in at least 135 minutes per week of physical activity. In 2004-2005, schools are required to offer PE to students in grades 6-8. Beginning in 2007-2008, students in grades K-5 are required to participate daily in physical activity for at least 30 minutes and students in grades 6-8 are required to participate in PE for at least 135 minutes per week. The requirements for grades K-5 refer to physical activity and permit recess to contribute to this requirement. Applicable statutes: Administrative Codes 74.2, 74.32, and 74.3, Tex. Educ. Code § 28.002.
Texas	Y	135	1993	Students in grades K-6 are required to receive instruction in PE. Applicable statute: U.A.C. R277-700-4. Schools are required to offer PE. The Nutrition and Physical Fitness Guidelines, established in 2005, recommend 150 minutes per week for elementary school students and 225 minutes per week for middle school students. Applicable statute: 16 V.S.A. § 906.
Utah	Y	0	1997	PE must be taught in all grades in elementary school and offered in middle school. Beginning in 2008-2009, a program of physical fitness of at least 150 minutes per week must be available to all students. Va. Code Ann. § 22.1-253.13:1, Code 22.1-207, Code 22.1-200
Vermont	Y	0	1981	Students in grades 1-8 shall receive instruction in PE. Applicable statute: Rev. Code Wash. (ARCW) § 28A.230.040
Virginia	Y	0	1980	Beginning in 2005-2006, students in grades K-5 are required to participate in at least 90 minutes of PE per week and students in grades 6-8 are required to participate in daily PE for one full period for one semester. The initial date of the PE requirement that schools provide PE is unknown, but predates 1993. Applicable statute: W. Va. Code § 18-2-7a
Washington	Y	0	1984	Beginning in 1988-1989, students in grades K-6 are required to participate in PE at least 3 days per week and students in middle school are required to participate in PE at least once per week. Applicable statute: Wis. Stat. § 121.02.
West Virginia	Y	90		Each school district shall provide educational programs that include PE. Students in grades 1-8 are required to be proficient in PE. Applicable statute: Wyo. Stat. § 21-9-101
Wisconsin	Y	3 days	1989	
Wyoming	Y	0	1999	

Sources: State statutes as found in LexisNexis and are cross-referenced with curriculum requirements published by states' Departments of Education, the National Association of State Boards of Education State School Health Policy Database, the 1993, 2001, and 2006 Shape of the Nation Reports, and the TFAH annual reports that began in 2004. The appropriate state statutes and amendments are listed in the notes column, if available. The year enacted is the earliest year with PE requirements known according to these sources. The reported PE requirements are applicable to students in public schools. The minutes column documents the required minutes of PE per week.
