

Chapter 3

Coming to America: Where Do International Doctorate Students Study and How Do U.S. Universities Respond?*

John Bound, University of Michigan & NBER

Sarah Turner, University of Virginia & NBER

It is well-known that the representation of foreign doctorate students at U.S. universities, particularly in science and engineering fields, has increased dramatically over the last three decades, rising to about 50% today from about 25% in the early 1970s. Much of the growth has come from new demand for advanced study in science and engineering from countries rapidly climbing a development trajectory, particularly South Korea, India, Taiwan, and – more recently – China. Growth in demand from foreign doctorate students has brought expansion at U.S. programs in many science and engineering fields. One basic contribution of this analysis is to provide a description of the trends in the distribution of foreign doctorate students across programs of different levels of quality, institutional control, and resources at public universities and universities outside the most highly-ranked. Expansion of doctorate education propelled by the flow of foreign students has been particularly marked outside the most highly ranked programs and at public sector universities. These differential trends highlight heterogeneity in the supply response among different universities. Whether changes in doctorate production are complementary to other university outputs such as undergraduate education provides evidence to explain the pattern observed across universities.

* We would like to thank Casey Cox and Xiaohuan Lan for exemplary research assistance. We are grateful to Michael Teitelbaum and Charles Clotfelter for excellent comments.

“Globalization” and “internationalization” are two of the most widely used (and overused) terms in contemporary higher education discourse. There is no question that doctorate education at U.S. universities has drawn an increasing number of students from around the world in recent decades. The growth of foreign students in U.S. doctorate education may produce a wide range of benefits and costs for universities. Foreign graduate students may enhance output in science and engineering, including research innovations, and contribute to teaching in undergraduate and professional education. As foreign students increase the supply of workers with advanced degrees, the flow into doctorate education may also change the wage structure for those with advanced degrees in science and engineering fields (Bound and Turner, 2006).

One point is clear: The expansion of foreign student participation in U.S. colleges and universities is far from monolithic. Expansion of doctorate education propelled by the flow of foreign students has been particularly marked outside the most highly ranked programs and at public sector universities.

In this analysis, we begin by describing the trends in doctorate attainment among foreign students at U.S. universities. We distinguish significant trends by country of origin and type of U.S. doctorate program. Our analysis demonstrates substantial shifts in country of origin over the last three decades among doctorate students, with the growth in foreign students coming largely from Asian countries, including China and India. Growth in foreign PhD students has come largely from expansion in program size, with this growth concentrated at programs at public institutions and those programs outside the most highly ranked.

The expansion of foreign participation in doctorate education is notably distinguished from expansion of foreign participation in other margins of U.S. higher education such as undergraduate and professional training. Not only does country of student origin differ markedly, but so does institutional destination and source of funding. Highlighting the comparison between the “internationalization” of doctorate education and undergraduate education serves to sharpen understanding of the impact of foreign doctoral students in the production of university research and undergraduate education. In section two, we present evidence relevant to these points.

Whether there is a link between the expansion of doctorate education generated by the growth of foreign students and changes in the number of undergraduates or their distribution by field across majors informs the assessment of the level of complementarity in the university production function. Increased foreign flows may serve to lower the cost of undergraduate degree production resulting in expansion in undergraduate majors; alternatively, the flow of foreign students may have substantial complementarity with university research outputs. It follows that those institutions with the highest benefits from extra products in research and teaching generated by additional graduate students will have been most likely to recruit for the expanding pool of foreign doctorate students. Data on changes in undergraduate concentrations and sources of funding for graduate students provide some evidence: in the main, effects of foreign flows on undergraduate degree production are small in magnitude while there is corresponding evidence that expansions in foreign PhDs in recent years have come with expansion in research funding. Doctorate student flows in the sciences are concurrently

outputs of university education and inputs to the production of research and, to a much more modest extent, teaching.

Section 1: Setting the Stage: The Flows of Foreign PhDs over Time by Country of Origin and University Destination

Basic Trends

While foreign students have been drawn to U.S. universities since the first part of the 20th century, there has been an unambiguous rise in PhDs awarded to students from abroad from the late-1950s to the mid-1990s, with considerable acceleration in growth concentrated in science and engineering fields beginning in the late 1970s.¹ The *Survey of Earned Doctorates* provides a census of doctorates awarded by U.S. universities by country of origin from the late 1950s to the present, and we use these data to show the broad trends by field in Figure 1.² In economics and engineering, degrees awarded to students from abroad have outnumbered those awarded to U.S. students for a number of years; in all but the life sciences, the foreign-born share has equaled or exceeded the share of U.S.-born PhD recipients.

¹ Note that even in the first part of the 20th century, universities in the United States attracted a substantial number of students from abroad, particularly in the sciences. In the period from 1936-1956 nearly 20% of PhDs in engineering and about 12% of PhDs in the life sciences were awarded to students who had completed undergraduate studies abroad. Bound, Turner and Walsh (2008) and Blanchard, Bound and Turner (2008) provide additional discussion of long-term trends in doctorate receipt by country of origin; this introductory section draws substantially on these earlier papers.

² The Survey of Earned Doctorates is an individual-level census of recipients of doctorates at U.S. institutions. Because survey participation is often coupled with the formal process of degree receipt, response rates have been quite high. Note that we focus our analysis on trends in doctorate degree recipients though it would be conceptually preferable to examine all enrolled student; data on the latter group are much more limited in time horizon and do not allow for the examination of country of origin, see Survey of Graduate Students and Postdoctorates in Science and Engineering conducted by the National Science Foundation (NSF) and National Institutes of Health (NIH).

Focusing on explaining the rise in the participation of students from abroad in U.S. doctorate programs, Bound, Turner, and Walsh (2008) emphasize that expanding undergraduate attainment in countries like South Korea and India produced increased demand for U.S. doctorate education. In addition, sharp changes in political circumstances in countries like China opened a new port of entry to U.S. graduate education that had been largely closed in the 1960s and 1970s. A further explanatory factor on the supply-side of U.S. graduate education is that substantial increases in public support for science and engineering research (and, in turn, graduate education) generates a response that may be particularly strong among students from abroad.³

A point of emphasis in prior descriptions of the doctorate education market is that the pattern of international flows differs quite markedly by country of origin, program characteristics, and university control and resources (see Black and Stephan (2007) and Bound, Turner, and Walsh (2008) for further discussion). Understanding these patterns requires consideration of the nature of demand among foreign students and, significantly, the supply-side response of U.S. universities in the context of differential funding structures for graduate education and university research across institutions.

Changes by Country of Origin

³ When funding in the U.S. for science (and, in turn, graduate education in the sciences) increases, the pool of students from abroad with preparation in scientific fields who are well-positioned to shift into U.S. PhD programs may be relatively larger than the similar pool of recent BA degree recipients from U.S. universities in the sciences. As such, the elasticity of demand among foreign students may be somewhat larger than among U.S. students if foreign students are simply choosing where to attend graduate school rather than weighing the choice between a graduate program and an alternate profession. In turn, short term enrollment expansion in response to funding expansion may come disproportionately from foreign students.

There is considerable variation in the source of doctoral students from abroad by country of origin and the patterns of attendance by country have changed markedly over time in distribution and scale. Table 1 shows the distribution of PhDs from U.S. institutions in science and engineering fields by country of origin for the decade from 1966 to 1975 and the more recent decade from 1996 to 2005. Much of the growth has come from new demand for advanced study in science and engineering from countries rapidly climbing a development trajectory, particularly South Korea, India, Taiwan, and – more recently China. Grant and Stephan (2007) note the relatively recent concentration of doctorate students from these four Asian countries which now account for about 60 percent of doctorate recipients.

Why students from some countries are particularly likely to pursue doctorate education in the U.S. surely depends on opportunity costs. In general, demand for doctorate education will be lower for those students with more abundant home country opportunities and, in turn, students from countries with relatively substantial university systems will be unlikely to study in the U.S. unless they can attend top-tier doctorate programs.⁴ What matters for students potentially pursuing study in the United States is the expected return to a U.S. PhD program relative to the best alternative in the home country. Students in each country face a choice based on the expected benefit to

⁴ The decision by students from different countries to pursue doctorate education in the United States is in many respects similar to the occupational choice selection problem set forth in the Roy model (1951). Because options for post-baccalaureate study vary appreciably across countries, it follows that the opportunity cost of pursuing a doctorate degree at a U.S. university varies among countries of origin. The result is that there are differences across countries in the total share of a nation's PhD recipients trained in the U.S. and variation in the representation of students by the quality of graduate programs in the U.S. The predictions we outline follow from the case where expected success as a PhD in the home country and the U.S. are positively correlated and the variance in returns is greater in the U.S. than the home country (e.g. the rewards to a top mathematician relative to a median mathematician will be greater in the U.S. than in home country). To this end, U.S. programs tend to be dominant in the top tail of the international distribution of program quality.

doctorate study in the U.S. and an expected return to persistence in the home country, which may include attending graduate school in the home country or pursuing some other vocation. Home country university systems differ and, as a result, the opportunity cost of pursuing a doctorate degree at a U.S. university varies among countries of origin. What is more, receipt of a doctorate from a U.S. university may well provide increased opportunities for employment in the U.S.⁵

In the cross-section, both the level of undergraduate degree attainment in foreign countries and the extent to which there are established doctorate-level programs in these countries have a substantial effect on the flow of PhD students to U.S. institutions. Countries without large university systems but with recent expansion in undergraduate attainment will have the greatest representation of doctorate students at U.S. institutions; students from these countries will also be represented in other well-developed university systems such as the U.K., Canada and Australia. To this end, it is not surprising that the ratio of PhDs awarded by U.S. institutions to home country institutions is high for countries like China (0.5), South Korea (.3) and India (.75) relative to European countries like France (0.013) or the U.K. (0.003) (Bound, Turner and Walsh, 2008, Table 1).

Foreign PhD Flow by Program Rank

For countries in which forgone opportunities are close to those in the U.S. – e.g., countries with large and well-established university sectors -- only a select few

⁵ Most foreign students hold F-status (student) visas while in school and, to work in the U.S., requires adjusting the student visa to the H1B status for high-skilled visa employment with the assistance of a institutional sponsor. As such, limited provision of visas and the restrictions related to H1B employment often leave foreign doctorate recipients with a more limited set of employment options than permanent visa holders and U.S. residents. Using an exogenous change in visa status associated with the Chinese Student Protection Act of 1992, Lan (2008) shows that permanent visa holders are about 24% less likely to take post-doctoral positions than temporary visa holders.

individuals will pursue graduate studies in the U.S. These individuals will be among those with relatively high ability and receive admission offers from some of the best programs in the U.S.⁶ In contrast, individuals from countries with much more limited higher education systems will have fewer opportunities for graduate study in their home countries and will be much more likely to choose to pursue graduate study at a U.S. university. In turn, these individuals may choose to come to the U.S. to pursue studies at programs outside the most highly ranked departments. To illustrate, the proportion of a country's PhD recipients receiving degrees from top-5 programs differs markedly across countries (and, to some degree, over time). For a number of Asian countries – notably Taiwan, South Korea, and China – PhD recipients in science are underrepresented in the top-5 departments and are much less likely to receive their degrees from these programs than PhD recipients from the U.S. in these fields. For example, while students from China are about 15.5% of all chemistry PhDs, they are only 5.3% of degree recipients from top-5 programs. At the other extreme, students from Canada and European countries tend to be represented in the top programs in shares in excess of their overall representation among PhD recipients from U.S. universities.

Over time, much of the growth in doctorate education has come outside the most highly ranked programs and, in turn, expansion in foreign doctorate receipt at U.S. institutions has been most concentrated outside the most “elite” or highly ranked programs. Figure 2 presents trends in doctorate awards to PhD in selected fields

⁶ A related implication is that the average “quality” or achievement of students and the associated graduate programs selected of PhDs receiving PhDs in the U.S. from a particular country is inversely related to the share of a country's potential doctorate students completing advanced study in the U.S. Less formally, students from a country like France receiving PhDs in the U.S. will likely to be among the best in their home country cohorts and attend the very top-tier doctorate institutions like MIT and Stanford, while students from a country like Turkey will be spread among a broader range of U.S. institutions as their home country options are more limited.

distinguishing programs in the top 15, ranks 16-30, ranks 31-50, and outside the top 50 and unranked. What is unambiguously clear is that in chemistry, physics and biochemistry, foreign degree expansion is concentrated outside the top-50 and starts a dramatic upward trend in the 1980s. In engineering, expansion is clear across all ranks though is nevertheless greatest outside the most highly ranked programs.

Expansion of Doctorate Education by Type of University

The U.S market for doctorate education is differentiated and highly stratified. Of the more than 3,000 four-year institutions of higher education, 413 universities in the United States awarded doctorates in 2002, with the mean number of degrees per institution 97, and the median number 38 degrees. Overall, production is relatively concentrated, with 20 institutions awarding 27% of the 2002 total of 39,955 degrees.⁷

Both private and public universities award PhDs, with public universities dominant in the number of institutions awarding degrees and the scale of doctorate programs. In 2005, public universities awarded over 15,000 degrees in science and engineering fields, compared to about 6500 degrees awarded by private universities; this margin has grown appreciably since 1960, when the comparative totals were 2989 and 2011 doctorate degrees awarded by public and private universities respectively. At the same time, a small number of “elite” private universities often occupy the top program rankings, though there is unquestioned competition between public and private

⁷ While this concentration is considerable, it is appreciably less than at the start of the century or the middle of the 20th century. The interval of expansion in U.S. higher education between 1950 and the early 1970s brought many “new entrants” to the higher education market. Focusing on the interval between 1958 and 1972, Bowen and Rudenstine (1992) document the extraordinary growth in the number of institutions and departments operating PhD programs. In economics, the number of PhD-granting institutions increased nearly 90% from 57 to 108 while in mathematics the number of programs increased more than 130% from 60 to 139.

universities for faculty, students, and resources. While the “products” of graduate education at public and private universities are widely seen as substitutes (PhDs from the University of Michigan compete with PhDs from Yale and the University of Pennsylvania for academic jobs), the financing and organization of private and public universities are sufficiently different that we might expect quite different institutional response to increased demand from foreign students. Substantial subsidies from the state, combined with a much larger scale of undergraduate education, distinguish public universities from private universities, potentially affecting responses to increased demand from foreign students.

Figure 3 presents broad trends in the number of doctorate degrees awarded by public and private institutions, with the further distinction by Carnegie classification.⁸ In each graph, there are broadly two regimes of expansion – a peak in the late 1960s and a subsequent upturn in the 1980s – with the relative magnitude of fluctuations over time differing by type of institution. Private research 1 and public research 1 universities have experienced more muted changes than the other institution types in the number of doctorates awarded. A clear point from the graphs is that while the early expansion was fueled by a substantial rise (and then contraction) in domestic PhDs, much of the growth in the later period comes through the expansion in the number of foreign PhD students in the science and engineering fields. Indeed, at all but the institutions in the “doctorate”

⁸ We employ the Carnegie codes (as classified in 1994) to distinguish broad types of institutions. The primary categories are:
Research Universities I: Award 50 or more doctoral degrees¹ each year. In addition, annually more than \$40 million in federal support.
Research Universities II Award 50 or more doctoral degrees¹ each year. In addition, they receive annually between \$15.5-million and \$40-million in federal support².
Doctoral Universities I & II Award annually at least 10 doctoral degrees--in three or more disciplines³ -- or 20 or more doctoral degrees in one or more disciplines.

category, the number of PhDs awarded to U.S. residents only increased modestly from 1980 to the present. Strikingly, the number of foreign PhD recipients increased by a factor of 3.25 in the public sector overall and 5.15 in the public “doctorate” sector. In the private sector, expansion in foreign PhDs has also been a significant force, with increases of 230% in the Research I sector, 390% in the Research II sector, and 270% in the Doctorate sector.

One notable distinction between public and private universities is the greater emphasis of the former in the “applied sciences.” The unique integration of basic research, professional training and science complementing local industry is fundamental to American public universities and foundational to the development of mass higher education at the start of the 20th century (Goldin and Katz, 1999). Doctorate programs in areas related to agriculture and engineering may be of particular interest to students from developing economies. As such, the relative concentration of foreign students at public universities is not surprising.

Focusing the discussion to consider specific institutions helps to sharpen understanding of the flow of foreign students at the PhD level. Table 2 presents a listing of PhDs awarded in total and to foreign students in the most recent decade and, as a point of comparison, the decade of 1966-75. Notably, the institutions that enroll the largest numbers of foreign students at the doctorate level are not coastal universities in traditional immigrant hubs like New York and Los Angeles but the large, public land grant universities including Texas A&M, Purdue, the University of Illinois and Ohio State. Part of this response is surely due to the greater concentration of public universities in the applied sciences, particularly engineering, as these fields may have

close ties to local industries while are also of greatest demand among foreign students from developing countries.

The Question of “Crowd Out”: Evidence and Supply Elasticity in Doctorate Education

While there is no question that foreign participation in U.S. doctorate education has increased, it is less clear whether this expansion represents net new doctorate awards or some displacement of potential U.S. doctorate students. The growth of foreign students among overall PhD recipients and PhD recipients from U.S. institutions affects the flow of potential U.S. doctorate students through two potential channels. First, U.S. students may face increased competition for “slots” or admission to graduate programs. At the most competitive graduate programs, where there is typically considerable excess demand for enrollment, the admission of additional foreign students is likely to be accompanied by reductions in admissions of domestic students. Second, beyond potential “crowd out” effects in higher education, the overall growth in the number of foreign doctorates (both those who obtained their degrees in the US and those who migrated after receiving their degrees) is likely to have had a substantial effect on the labor market returns to PhD awards in science (Bound and Turner, 2006).

Measuring the degree of direct “crowd out” in graduate education is not straightforward empirically: Changes in the rate at which U.S. students complete PhD programs may reflect both increased demand among foreign students and other factors such as funding shocks which would lead to increases in scale of graduate programs.

While a number of studies have attempted to estimate the magnitude of potential crowd-out effects, there is little conclusive evidence to support substantial crowd-out effects.⁹

The case of the sharp increase in demand among Chinese graduate students beginning in the early 1980s presents a relatively clear opportunity to assess the adjustment of the U.S. market to a sharp demand shock. Focusing on the field of physics as an illustration, consider the change in doctorate completion by year of program entry for Chinese students, other foreign students and U.S. residents (Bound, Turner, and Walsh, 2008). At top ranked programs, the number of additional students from China is small and there is little discernable change in the overall number of PhDs awarded. Outside the most highly ranked programs, the number of Chinese students receiving PhDs from universities outside the top-50 increased from 7 to 202 between the 1980 year of graduate entry and the 1985 year of graduate school entry. Notably, this large “shock” produced no notable decline in PhDs awarded to U.S. students at these institutions, with this number actually rising slightly from 164 to 199, while the number of students from other countries receiving PhDs also rose over this interval of graduate school entry. Data for other fields show similar patterns. Remarkably, this large cohort of Chinese students had no discernable impact on the number of U.S., or for that matter, other foreign students receiving PhDs in the sciences. The example produced by the particularly large and rapid influx of Chinese students in the early 1980s may be hard to reproduce in other

⁹ Using data from the *Survey of Graduate Students and Postdocs* and variation within academic departments, Regets (2001) finds a largely positive association between enrollment of U.S. students and foreign students. Borjas (2007) uses within institution variation in graduate student enrollment measured in the IPEDS surveys and finds a negative effect of foreign enrollment on the level of enrollment of white men, though little effect on domestic enrollment in aggregate. Finally, Zhang (2004) used the *Survey of Earned Doctorates* and reports essentially no evidence of crowd-out of native students associated with additional PhDs awarded to native students. A limitation of this broad line of inquiry is that expansion in the representation of foreign students in U.S. graduate programs may well be endogenously related to other factors such as the availability of funding which simultaneously affect the demand for graduate students.

periods both given its scale and its arrival during a period in which funding for the sciences in general and the physical sciences in particular, was expanding rapidly. Nevertheless, this evidence does suggest that it is plausible that realized expansions in the representation of foreign doctorate students need not crowd out domestic doctorate attainment by U.S. students.

Our conclusion is that outside the most highly ranked programs, many doctorate programs are relatively elastic in scale.¹⁰ “Supply elasticity” at the PhD level is much greater outside the top-tier universities, particularly outside the top-50; these are institutions with programs often below the minimum efficient scale, many of which experienced sharp declines in domestic student interest in the mid-1970s. In turn, at the universities and programs where the expansion of foreign doctorate recipients has been the largest, our interpretation is that “crowd out” is minimal in the sense that additional doctorate recipients from abroad do not substitute for domestic PhD production at the institutional level. Proceeding from this assessment, we compare the influx of foreign doctorate students to undergraduate students from abroad and then turn to the consideration of how the expansion of doctorate education of non-U.S. students at U.S. universities affects university outputs in research and undergraduate instruction. In Section 3, we return to the question of how (or why) supply can be described as “elastic” in the graduate education market where additional students are generally not accompanied by additional tuition revenues but instead require additional expenses in terms of research support.

¹⁰ Indeed, for the programs that are unranked or ranked very modestly, the period of growth in the 1960s and early 1970s represented both expansion in scale and the entry of new programs; the entry of new programs in this category was extraordinary, with a threefold increase in the primary science fields. As the market contracted in the 1970s and then expanded in the 1980s, the adjustment came in terms of the scale of programs, with apparently few programs either exiting or entering the market.

Section 2: The Differentiation of Doctorate Education and Undergraduate Education for Foreign Students

To understand the distinct context of the participation of foreign students in doctorate education, it is instructive to examine broad comparisons with the flow of international students to U.S. undergraduate programs. Overall, one might be tempted to regard the flow of undergraduate students and graduate students from abroad as closely coupled trends. Figure 4 shows total enrollment of graduate and undergraduate students from abroad at U.S. colleges and universities from 1955 to 2005; the trends are largely overlapping and the levels for 1965 and 2000 are close to identical. Yet, this broad correlation hides substantial differences in country of origin, source of support, and institutional destination. Moreover, foreign students are a much larger share of doctorate recipients from U.S. institutions than undergraduate degree recipients and, as such, shifts in the pattern of matriculation among foreign doctorate students would likely have substantial equilibrium effects and implications for university research.

College and University Choices in the U.S.

Graduate students are much more likely to be concentrated at public universities, while undergraduates are more likely to gravitate to private institutions. An obvious – if tautological – explanation is that many private institutions such as liberal arts colleges -- don't have substantial graduate programs in the sciences or don't have graduate programs at all. Yet, the distribution of non-citizens enrolled at the undergraduate level at U.S. institutions is appreciably different than domestic students, as shown in Table 3. While

non-citizens are about 2.1% of aggregate undergraduate enrollment, these students comprise about 3.2% of the undergraduate body at private institutions, where they are even more likely (4.4%) to be represented among the institutions awarding PhD degrees.

A number of institutions in the U.S., such as Boston University, Northeastern University in Massachusetts and Babson College in the northeast, actively recruit foreign students. At Babson College about one quarter of the students are from abroad while at Boston University, international students are typically about 7% of the freshman class (Jan, 2008; Schworm, 2008). Some in college recruiting have posited that favorable exchange rates have increased the attractiveness of U.S. institutions, while concurrently U.S. universities have been more aggressive recruiting from abroad.¹¹ While a select few institutions are able to offer full financial aid to international students, much of the impetus for overseas recruiting is tied to the capacity of students to pay substantial tuition expenses either directly or through home country fellowship support.

Country of Origin

The countries that send a high fraction of students to study in the U.S. at the undergraduate level are very different from those with large flows of students to U.S. doctorate education or graduate school more generally. While the overall ratio of foreign undergraduate to foreign graduate students was about .9 in 2007, there are many countries well above and well below this ratio, as shown in Table 4. The countries with disproportionately high representation of undergraduates enrolled in the U.S. relative to graduate students tend to be those with the substantial income inequality. Oil rich

¹¹ A July article (Schworm, 2008) quotes a number of students as benefiting from the weak dollar, with the price of a U.S. education declining relative to substitutes in the U.K. For example, Martin Prochazka a student from the Czech Republic notes “It wasn’t the only reason but it was pretty important. I checked into London but it was twice the price.”

countries are well-represented in this list. At the other extreme, countries with relatively high representations of graduate students include countries like China and India that are on rapid development trajectories, with modest existing university infrastructure. In addition, European countries like Italy and France with well-developed state higher education systems appear much lower on the list as few undergraduate from these countries pay to study in the U.S. while very top tier students may pursue graduate study in the U.S.

The data certainly suggest a model in which capacity to finance undergraduate education is a determinant of undergraduate enrollment. Indeed, there is some evidence that commodity price shocks – particularly oil – are an important determinant of undergraduate enrollment flows from a number of Middle Eastern countries. Figure 5 provides an illustration of the fluctuation in enrollment from oil-rich countries in association with oil prices. In these countries, it may well be that American undergraduate education is a luxury good, with changes in income leading to increased enrollment rates. But, a college education is certainly more than a consumption good, and it seems likely that access to capital afforded by positive oil shocks generates financing for higher education for students from these countries, as there are certainly many more well-qualified students from other countries abroad who would apply to U.S. universities if they were able to finance the tuition expenditures.¹²

¹² To be sure, a small number of the “super-elite” colleges and universities in the U.S. are able to offer need-blind admission and full financial aid to international undergraduate students; these institutions include , MIT, Harvard, Princeton, Dartmouth, Williams, and Middlebury, with most of these institutions opening aid to international students around the year 2000. See <http://www.edupass.org/finaid/undergraduate.phtml> for a list of universities that offer significant financial aid (both need-based and merit, but not athletic) to international students.

One testable implication is that overall flows of graduate students should be much less sensitive to currency shocks and prices of major export goods (e.g., oil) than flows of undergraduate students. Indeed, as we will pursue in more detail in subsequent sections, it is not home country financing but U.S. university financing that is the primary source of support for foreign doctorate students; as such, we expect research funding and other determinants of university resources to be primary in determining the number of foreign doctorate students accommodated by U.S. universities.

Sources of Support

It follows that we should expect to see undergraduate students heavily dependent on “own” support, paying full tuition at undergraduate institutions while graduate students are more likely to rely on financial assistance through teaching appointments, research assistantships, and fellowships. Indeed, even as there may be many students from abroad who would like to borrow to finance investments in both undergraduate and graduate education in the United States the absence of well-functioning international capital markets likely makes such actions impossible.

Charting the sources of support for both undergraduate and graduate students is a daunting challenge and the data presented below are subject to some non-trivial problems, often recording support in broad terms like “primary” or based on imperfect institutional recording of funding sources. As international flows of students increase, better tracking of student enrollment, degree completion, and sources of support is imperative to account for the benefits and costs of “globalization” at U.S. colleges and universities.

Overall, the data from Institute of International Education (IIE) shows that among undergraduate students, 81.6% of foreign students finance their studies through “personal and family funds.”¹³ When we focus on doctorate students in the sciences, the distribution of funding sources is dramatically different, only about 5% of foreign students relying on “own” sources as their primary support mechanism in graduate school in recent years. Indeed, foreign students are somewhat less likely to rely on own support for graduate study than their domestic peers, presumably because the latter have greater access to credit markets and family resources so still may have an option of attending even if they are not fully-funded. In turn, foreign students are somewhat more likely to have an “employment” source of support – either teaching assistantship or research assistantship – than their domestic U.S. peers, while they are somewhat less likely to be supported by fellowship funding. Note that the proportion of foreign students funded through research assistantships rose particularly markedly from the decade of the 1980s to this present, with this shift particularly prominent for students receiving their degrees from public institutions as shown in the second panel of Table 5.

Our comparison of students from abroad at the doctorate level and undergraduate level leads to several propositions which motivate more focused consideration of the foreign students in graduate education in the next section. First, the fact that undergraduates typically pay for most if not all of the cost of attendance leads to quite different distributions of country of origin by level of study. In addition, the implication of the large share of students – particularly foreign students – who are funded through their doctorate studies is that their presence provides substantial benefits to the university

¹³ *Open Doors 2007* “Table 15 International Students by Primary Source of Funding 2005/06 & 2006/07.”

in terms of teaching and research. Whether foreign doctorate students impact undergraduate production as well as research is the subject of the next section, along with the consideration of whether institutions in different resource positions and those in public rather than private control employ new flows of foreign graduate students differentially.

Section 3: The Effects of the Expansion of Foreign Doctorate Students on Undergraduate Education

That so many graduate students in general and foreign doctorate students in particular support their studies with teaching and research appointments is an implicit demonstration of the complementary role played by graduate students in the university production function. We are interested in addressing whether the complementarity is stronger in teaching or in research. Whether researchers (and the consumers of research) or undergraduate training are the most likely beneficiaries of additional graduate students represents an important dimension of university resource allocation.

While we stop short of a full model, it is useful to consider the comparison of additional demand among foreign undergraduates (where tuition price effectively clears the market) to additional demand among foreign graduate students. In the case of increased demand among graduate students, there are likely to be spillovers to other dimensions of university production, including research and undergraduate education. Assume the presence of some economies of scope in the university production function such that the total cost (TC) of production of graduate education along with

undergraduate education and research must be less than the production of these activities separately, implying the following expression is positive:

$$SE_G = \frac{TC\{0, Q_G, 0\} + TC\{Q_U, 0, Q_R\} - TC\{Q_U, Q_G, Q_R\}}{TC\{Q_U, Q_G, Q_R\}}$$

where Q_G is the number of graduate students enrolled, Q_U is the number of undergraduates and Q_R is the quantity of research produced. If additional doctorate students represent “exogenous shifts” in the sense that at each level of financial support more students are willing to enroll, the effective price of complementary activities declines and we would expect more undergraduate output or research output in proportion to the degree of complementarity. Similarly, if research funding increases (e.g., positive government science shock), we would expect an increase in graduate enrollment to the extent that graduate education and research are complementary.

Our original contribution in this paper is to explore the link between graduate flows and undergraduate flows, noting that a number of other researchers have tackled the difficult question of the link between foreign graduate flows and research output (see Stephan and Black 2007; Stuenkel, Mobarak and Maskus, 2007).

Undergraduate Teaching and Doctorate Education

One potential link to the expansion of doctorate training in the sciences is growth in undergraduate education. Without establishing strict causality, complementarity in production between undergraduate and graduate education in the sciences would be indicated by a positive link between enrollment and degree attainment in the two areas. One mechanism is that increased local undergraduate demand would lower the cost of

recruiting additional graduate students or, alternatively, a large influx of graduate students would make it attractive to expand undergraduate education. In turn, undergraduate education in the sciences might be affected on two margins: 1) overall increases in student numbers (e.g. expansion proportionate with the university) and 2) a relative increase in undergraduate majors in fields associated with the expansion of graduate education.

To quantify the link between graduate flows and undergraduate flows, we are interested in estimating relationships of the form:

$$\ln UM_{ijt} = \alpha_i + \delta_j + \lambda_t + \beta \ln PhD_{ijt} + \varepsilon_{ijt}$$

where i indicates field, j indicates university, t indicates year, UM specifies undergraduate majors and $PhDs$ indicates the scale of the doctorate program. In turn, the estimated parameter β is the elasticity of undergraduate majors in field i with respect to additional PhDs in field i . One explanation for concurrent changes in PhDs and undergraduate majors is aggregate university expansion. Our interest is particularly focused on how changes in doctorate program scale generated by (potentially) exogenous shifts in foreign students affect undergraduate concentrations. To capture these changes we can focus on foreign PhDs as the key explanatory variable, what might be called the reduced form relationship, or present IV estimates with foreign PhDs serving as the instrument for all PhDs as increases in participation from foreign students are plausibly (though perhaps not entirely) a result of home country changes exogenous to the U.S. education market.

Table 6 presents estimates over the extended period from 1970 to the present of the effect of PhD expansion in the sciences on science BA levels (top panel) and science

BA shares (bottom panel). Our within institution estimates tend to be precisely estimated, with effects of very modest magnitude. The IV estimates suggest elasticity estimates of 0.09 at public institutions and 0.12 at private estimates, implying that a 10% increase in science doctorate cohort size would be associated with an increase in undergraduate majors on the order of 0.9% and 1.2%, respectively. Probing these estimates more deeply, we note that the estimate for private institutions is much smaller at the “Research 1” institutions than at the other types of private doctorate institutions. In the bottom panel, where we address the effects of PhD flows on relative concentrations of undergraduate majors in the sciences (share of science majors within the institution), we find essentially no significant effects.

In discussing these results, it is worth emphasizing that while the results may be unsurprising to many observers they contribute important evidence to an otherwise speculative discussion. One explanation for the very modest effects of PhD supply shocks on undergraduate education is that there may be little net change in course offerings or reductions in student faculty ratios that would make science majors more attractive to undergraduate students. New graduate students employed as teaching assistants may simply substitute for line faculty (who, in turn, may allocate more time to research) or adjunct faculty. A second, and perhaps more persuasive argument is that additional graduate students – particularly those from abroad – adding to program size may not be deployed to teaching functions but research functions; we pursue this latter hypothesis below.

Still, there is sufficiently long history of discussion of the role of graduate students in undergraduate teaching and the expansion of university programming that we

investigate the extent to which the circumstances of the 1960s were different fundamentally than those operating since the 1980s. Figure 6 shows the long trend in BA degrees awarded and PhD degrees awarded in the U.S. over a century, and the broad correlation is unmistakable. Yet, a closer look at the data for doctorate granting institutions -- that is focusing on BA degrees awarded in the sciences by corresponding institutions -- shows a much different correlation (or lack thereof) in Figure 7. While undergraduate degree attainment continued to rise into the early 1980s, this was the period when doctorate programs were largely contracting; thereafter, contraction in undergraduate degrees corresponded with growing doctorate receipt (particularly among foreign students) in the 1980s. The most recent period shows little link between undergraduate and graduate education in either the public or private sectors. Looking back to the period of the 1960s, it has been argued that the dynamics generating the robust growth in doctorate attainment and dramatic decline in doctorates awarded (particularly to U.S. residents) in the early 1970s can be attributed to a confluence of historical factors. Indeed, there is evidence that the elimination of 2-S military draft deferments for graduate study in the late 1960s, followed by erosion in the domestic academic labor market, dramatically slowed the rate of doctorate attainment among U.S. residents (Bowen, Turner, and Witte, 1992).

Research Funding and Doctorate Education

If additional doctorate students in the sciences – and, specifically, additional foreign doctorates – are not adding to the outputs in undergraduate teaching, it merits asking how the funding of these students aligns with the teaching and research functions (and outputs) of universities. As a caveat to this discussion, we note that the data

available on financial support of doctorate students in the *Survey of Earned Doctorates* is far from ideal. We observe the “primary source of support” over the graduate career rather than more informative measures of the level and composition of support; in addition, the “primary source” measure is only observed from 1977 to the present. Absent other sources of information, we start with these data to fix broad trends.

Table 7 presents the distribution of primary source of support for foreign and U.S. students by field and type of institution for broad field classifications in the sciences. Outside of economics, the share of both foreign and U.S. students reporting “teaching assistantship” as their primary source of support declines from the late 1970s to the current period, with these drops most marked in the physical sciences and engineering. As such, these data are largely consistent with the very small effects of expansion of doctorate education on undergraduate education reported in the prior section. It is worth noting that the field of economics – particularly at public universities – looks very different than the physical and life sciences in patterns of support. In economics, over 46% of foreign PhD recipients and 42.6% of PhD recipients from the U.S. at public universities relied on funding through teaching assistantships as the primary source of support in the most recent period of observation. In other scientific fields these shares are much lower and have been trending down, not up, over time, with TA positions serving as the primary source for less than 12% of doctorate recipients in the life sciences and less than 10% in engineering.

How then are doctorate students financed in the most recent decades if they are decreasingly engaged in undergraduate teaching? While there are substantial differences in starting levels across fields, we see clear increases in RA support for foreign graduate

students. If the share of foreign PhD students funded by research positions increases while the number of foreign students is also increasing, it follows that the total number of research assistant positions held by foreign students must also be increasing. Table 7 shows that this shift in source of support is particularly strong at public institutions (again, excepting economics). For economics, it is likely that there are fewer scale economies in research that allow for the employment of graduate students in labs or on research grants; in turn, demand for undergraduate courses may have expanded while demand in the sciences more generally has remained flat.

For U.S. doctoral students, the clear shift is toward fellowship funding as a primary source of support over the last three decades. If fellowship support is increasingly needed to attract U.S. doctoral students while foreign students are willing to attend with research assistantships, the price to institutions of attracting an additional student to study in the sciences may be higher for domestic applicants than the parallel price for foreign students. Yet, the data available to us do not distinguish between fellowship support provided by external sources (which may be restricted to domestic students) and fellowship support provided through the funds of universities. This distinction in source of fellowship funding is critical to the interpretation of the differential trends in sources of support for U.S. and foreign students. External awards (e.g., NSF awards to individuals) are implicit subsidies to universities in the production of graduate education while university-supported fellowship awards are direct institutional costs without the direct obligation to participate in university research (as distinguished from independent research) that is implicit in research assistantship appointments.

Conclusion and Next Steps

Doctorate production in science and engineering fields plainly intersects with the research and undergraduate teaching functions of the university. Preliminary evidence presented in this paper suggests that the expansion of foreign doctorate attainment in the sciences at U.S. universities has been largely aligned with the research function at universities. Other researchers are actively addressing the important related questions associated with the productivity of foreign doctorates in the U.S. research enterprise, considering the extent to which expansion in the presence of foreign students increases publications, patenting, and innovations.

“Who pays?” and “who benefits?” are fundamental questions in higher education policy. At the undergraduate level, the answer is relatively straightforward: undergraduate students (and their parents) pay for higher education through tuition and receive largely private benefits.¹⁴ Thus the decisions of foreign students to pursue undergraduate education in the United States are determined largely by capacity to pay. At the graduate level, it is much more common for universities to support students through research and teaching positions, as well as fellowships. For students from abroad, these financing sources are likely to be crucial in facilitating attendance, in the absence of well-functioning capital markets.

¹⁴ To be clear, this statement is relative in the sense that tuition price is likely to be well-below the actual cost of provision at many undergraduate institutions (hence many “full pay” students pay less than full cost); in addition, beyond the private benefits to higher education that accrue in the form of improved earnings there may be some external benefits to consider in a full calculation.
