Chapter Title: The Servicification of the US Economy: The Role of Startups versus Incumbent Firms

Chapter Author(s): Mercedes Delgado, J. Daniel Kim, Karen G. Mills

Chapter URL:

7.1 Introduction

The past few decades have shown a fundamental shift in the US economy from manufacturing toward services (figure 7.1). This trend has raised concerns that the shrinking manufacturing sector may hamper the overall rate of innovation. However, unprecedented growth in one important subcategory of services—Supplemental Chain Traded Services—suggests a more optimistic view. SC Traded Services (i.e., service inputs sold to organizations) represents a set of industries that account for a disproportionately high share of science, technology, engineering and math (STEM) jobs in the US economy (Delgado and Mills 2020). The economic importance of these services is evidenced in the growth of such industries as computer programming, data processing and hosting, design, and logistics services (Bitner, Ostrom, and...
While prior studies have documented the shift in the US economy from manufacturing to innovative services (see, e.g., Delgado and Mills 2020; Eckert, Ganapati, and Walsh 2019), understanding the causes and sources of this transition is in its infancy. In particular, little is known regarding the types of firms—startups or established firms—that are driving the transition to SC Traded Services. In this chapter, we explore the role of three types of firms as potential drivers of growth in these innovative services. First, we analyze the entry and growth of new and young firms enabled by new technology and data, like Okta and Rapid7. Second, we examine the transformation of incumbent manufacturing firms toward services over the past few decades, including Cisco, IBM, Intel, and Xerox (Baines et al. 2017; Lodefalk 2013; Vandermerwe and Rada 1988; Visnjic Kastalli and Van Looy 2013). Third, we explore the growth of incumbent SC Traded Services firms, such as Microsoft and Accenture.

To implement our analysis, we primarily use the Longitudinal Business Database (LBD) of the US Census Bureau, which is a panel dataset of all establishments in the US economy with at least one paid employee. The longitudinal nature of the LBD allows us to distinguish new and young startups from incumbent firms and to track important business characteristics, including employment and payroll. We then categorize each establish-
ment’s underlying industry using the categorization developed by Delgado and Mills (2020). Our sample covers all US establishments between 1998 and 2015, capturing the economic activity (employment and wages) in each sector by each firm type.

In this chapter, we focus on the types of firms and industries that are leading the transformation into high-wage, high-growth services. Our analysis provides a foundation for developing innovation and entrepreneurship policies specifically focused on building the skills and innovation ecosystems that better support innovative services, as this sector represents an important source of good jobs in the future.

7.2 Pessimistic View of the US Economy: Manufacturing vs. Services

Many US politicians and policymakers appear to believe that the best way to rebuild the economy is to bring manufacturing back. The innovation debate has remained largely centered on manufacturing because it accounts for the vast majority of patents, while services tend to be viewed as low-technology and lower-wage. The focus on manufacturing has resulted in a pessimistic view of the economy reflecting the decline in manufacturing jobs, which has been attributed in part to an increase in imports from China (Acemoglu et al. 2016). From 1998 to 2015, manufacturing employment declined by more than 32 percent, while services grew by 25 percent (figure 7.1). However, the pessimistic view about innovation is misleading: manufacturing currently comprises only about 9 percent of employment, and services are extremely heterogeneous—ranging from engineering and cloud computing to retail and restaurants. This chapter focuses on the hidden and growing role of suppliers of services in driving innovation and the jobs of the future.

7.2.1 A New Framework: The Supply Chain Economy

In recent work, Delgado and Mills (2020) develop a new innovation framework that focuses on the suppliers of goods and services to businesses and the government: the “supply chain economy.” It includes businesses producing inputs (versus consumer products), such as semiconductors, cloud computing, design, and engineering services.

Suppliers are a source of innovation due to three important conceptual attributes. First, they create specialized inputs that can make the innovation process more efficient (Rosenberg 1963). Second, they tend to have numerous layers of buyer industries, so inventions developed by suppliers can diffuse broadly to multiple downstream industries. At the extreme, some innovative inputs (e.g., semiconductors) become general purpose technologies (GPTs) (Bresnahan and Trajtenberg 1995). Service industries, such as cloud computing and artificial intelligence, are becoming the next wave of GPTs (Brynjolfsson, Rock, and Syverson 2018; Cockburn, Henderson, and Stern 2018; Delgado and Mills 2020; Trajtenberg 2019). A third impor-
The crucial attribute of suppliers is that they fuel geographical clusters, which spur innovation through the generation of agglomeration benefits (Chinitz 1961; Delgado, Porter, and Stern 2014).

To quantify the role of suppliers in innovation and jobs, Delgado and Mills (2020) provide a new industry categorization: Supply Chain vs. Business-to-Consumer industries. Using the 2002 Benchmark Input-Output Accounts of the Bureau of Economic Analysis (BEA), they separate supply chain (SC) industries (i.e., those that sell primarily to businesses or government) from business-to-consumer (B2C) industries (i.e., those that sell primarily to consumers). They find that there is a distinct and large supply chain economy that accounts for 43 percent of US jobs (53 million) and for most STEM jobs and patents (87 percent) as of 2015 (figure 7.2).

In contrast to other industry categorizations that condition on industries that are STEM or knowledge-intensive (e.g., “knowledge-intensive business services” (Muller and Doloreux 2009); “advanced industries” (Muro et al. 2015); or “skilled traded services” (Eckert, Ganapati, and Walsh 2019), the supply chain industry categorization does not rely ex ante on innovation metrics. Industries that sell inputs to organizations are examined because of their conceptual importance for innovation, as described above. The empirical findings show that supply chain industries do, in fact, have a high concentration of innovative activity, as measured by STEM jobs and patents. Thus, the supply chain economy categorization reveals important insights on the sources of innovation in the US economy.

Fig. 7.2 Full supply chain categorization: Employment and STEM intensity, 2015

Source: Data from Delgado and Mills (2020); employment numbers from CBP 2015 data.

Note: Private-sector non-agricultural employment (excluding self-employed). Employment is in millions. STEM percent is the intensity of STEM jobs—the percentage of the subcategory jobs that are in STEM (e.g., 10.7 out of 100 SC jobs). Services includes non-manufactured goods.

1. SC industries are those with low sales to Personal Consumer Expenditures (≤ 35 percent); and B2C industries otherwise. Alternative SC industry definitions are tested in the appendix of Delgado and Mills (2020).

2. These alternative categorizations select industries based on particular innovation metrics, and therefore often include a mix of SC and B2C industries. For example, Eckert, Ganapati,
Delgado and Mills (2020) combine their categorization with two prior industry categorizations, Traded versus Local (Porter 2003) and Manufacturing versus Services, to analyze specific subcategories of the economy (see full SC versus B2C categorization in figure 7.2). They find that SC Traded Services are a large and distinct segment that is a key driver of innovation. This subcategory encompasses more than 200 industries, including data processing and hosting, software, many professional services (like design, engineering, R&D, and advertising), financial, and logistics services. SC Traded Services constitute a significant part of the economy, with 20 percent of all jobs and 17 percent of firms. These services have the highest-wage jobs and are marked by the highest STEM intensity (17 out of 100 jobs are in STEM occupations), though interestingly, they account for relatively few patents (9 percent). Importantly, they have experienced fast growth in terms of jobs and wages during the 1998–2015 period (figure 7.1).

What could explain the high growth of these innovative service inputs? One answer is that these industries have many layers of buyer industries (based on the measure of industry upstreamness developed by Antràs et al. 2012). This attribute, together with high STEM intensity, can increase their ability to produce specialized inputs for distinct industries and to cascade and diffuse innovation. In an increasingly knowledge- and data-driven economy, many of these services, like cloud computing, have become centrally important.

What firms are driving the growth in SC Traded Services? We examine three types of firms that may be contributing to the growth: new and young firms (e.g., Rapid7 and ShipHawk); manufacturing incumbents (e.g., IBM and Intel); and service incumbents (e.g., Microsoft and IDEO). Understanding the types of firms driving this change is important, as each may require distinct policy initiatives to access skilled labor, capital, buyers, and other growth-enhancing resources.

7.3 Data: Mapping Firms by Sector and Age

In this study, the Longitudinal Business Database (LBD) of the US Census Bureau serves as the primary dataset. The LBD is a panel dataset of all and Walsh (2019) classifies as Skilled Tradable Services the NAICS codes 51 (Information), 52 (Finance and Insurance), 53 (Real Estate and Rental and Leasing), 54 (Professional, Scientific, and Technical Services) and 55 (Management of Companies and Enterprises). These services include 88 SC industries and 55 B2C industries (six-digit NAICS-2012 code). Among the 218 SC Traded Services industries in Delgado and Mills (2020) only a subset of 67 industries is also included in Eckert, Ganapati, and Walsh (2019)’s Skilled Tradable Services. Industry categorizations based on innovation metrics can be very useful, but they do not explore the conceptual reasons that an industry might be, or evolve to be, more STEM or innovation intensive.

3. Traded industries are those that sell their output across regions and countries, as opposed to industries that primarily serve the local market (e.g., retail). This categorization was initially developed by Porter (2003).

employer establishments in the US economy. The LBD provides important establishment-level characteristics, including employment, payroll, industry, and location. Spanning 1976 to 2015, the LBD covers all industries in the private non-farm economy and every state in the US. While the underlying observations are at the level of the establishment, the LBD assigns a unique firm identifier to each establishment—a useful feature for tracking establishment-level activity for firms with multiple establishments.5

We also use the 2017 National Establishment Time-Series (NETS) database to examine and illustrate three incumbent firms that have been increasing their service activities: IBM, Intel, and Microsoft. The NETS database (by Walls & Associates, in collaboration with Dun & Bradstreet) is public and provides establishment-level employment data for many firms but with some limitations in its coverage and estimates.6

Our analysis is at the establishment level. Each LBD firm is decomposed into its portfolio of establishments. We then aggregate economic activity at the sector level by summing up across all establishments in a given sector (e.g., manufacturing vs. services). Therefore, a multi-unit firm with establishments spanning multiple sectors contributes to each sector based on its establishment-level activity. In measuring economic activity, we primarily use employment and payroll (adjusted to 2015 USD).

7.3.1 Firm-Level Attributes: Primary Industry and Age

As mentioned above, in measuring aggregate activity, we use establishment-level statistics to capture a multi-unit firm’s contributions across multiple sectors. However, for analyses that examine firms in certain sectors (e.g., incumbent manufacturing firms in 1998; see figures 7.6–7.9 later in the chapter), we define each firm’s primary industry using its firm-industry employment.7 We then use the primary industry (six-digit NAICS) to classify whether an incumbent firm is in Manufacturing or SC Traded Services.

We also use the LBD to separate new firms (age 0), young firms (ages 1–10), and mature or incumbent firms (ages 11+). These cutoffs are based on the first year in which a firm’s establishment appears in the LBD. It is important to note that a nontrivial share of establishments have a missing

5. See Jarmin and Miranda (2002) for more information regarding the LBD.
6. The NETS dataset follows over 60 million establishments during 1990–2017. Data are available for the whole country. Informed by Delgado and Mills (2020), we acquired data for a selected group of firms. While the NETS data are useful for examining firm dynamics, the dataset also has some limitations, including that data are often initially imputed for new establishments, there is considerable rounding of employment, and short-term employment changes are not measured very accurately (see Neumark, Zhang, and Wall 2005).
7. Specifically, for each multi-unit firm, we first identify the two-digit NAICS sector that accounts for the highest share of the firm’s employment. Within this two-digit industry, we then identify the three-digit NAICS industry with the highest share of firm’s employment. This process is repeated until the six-digit NAICS industry is determined—the firm’s “primary” industry.
As a result, the overall levels in economic activity may be underestimated, but trends relative to 1998 should not be affected.

To quantify the economic activity in SC Traded Services in the US economy, we use the Supply Chain versus B2C Industry Categorization for six-digit NAICS (Delgado and Mills 2020). For most of our analyses, we report aggregate economic activity in each sector (e.g., service) by each firm type (i.e., new, young, and mature).

### 7.4 SC Traded Services: Employment and Wage Trends by Firm Age

The US economy has witnessed a puzzling contraction in the rate of entrepreneurship. While research has demonstrated an overall decline in startup activity (Decker et al. 2014), there has simultaneously been a gradual rise in high-quality startups (Guzman and Stern 2019). One hypothesis is that the

**Table 7.1 SC Traded Services: Employment and wages by firm type (new, young, mature)**

**Note:** The analysis of SC Traded Services by firm age uses the LBD. Firm age is a firm-level attribute based on the oldest establishment in the particular year. Total, Services, and SC Traded Services figures are sourced from Delgado and Mills (2020) and use the CBP data. Real wages in 2015 USD using CPI-U (All Urban Consumers; BLS).

(six-digit) industry in the LBD (e.g., see “unmatched” in table 7.1). As a result, the overall levels in economic activity may be underestimated, but trends relative to 1998 should not be affected.

---

8. The unmatched SC Traded Services employment primarily reflects LBD establishments with NAICS codes that are more aggregated (e.g., 4-digit) and therefore cannot be matched into the 6-digit NAICS industry categorization in Delgado and Mills (2020). In these cases, we can distinguish whether the establishment operates in Manufacturing versus Services, but cannot identify the type of service subcategory (e.g., SC Traded Services or SC Local Services). Some of these non-matches could be reduced in future work.

9. The full classification of the six-digit industries (NAICS-2012 definition) into these SC and B2C subcategories is available in Delgado and Mills (2020) in the supplemental online appendix B: Supply Chain and Business-to-Consumer Industry Categorization.
decline in new firm formation is concentrated in B2C Main Street services, but that high-growth startups are increasing in supply chain services that leverage STEM skills. Surprisingly, our preliminary findings suggest that this is not the case. We find a decline over time in the employment created by new and young firms in SC Traded Services as well as in total Services (figure 7.3).

Table 7.1 shows the level and growth in aggregate employment and payroll in the SC Traded Services sector for three firm types. Mature firms represent 11 percent of total US employment (with over 14 million jobs in 2015), followed by young firms (with 3.5 million jobs) and new firms (with barely 0.3
million). In terms of wages, all SC Traded Service firms have higher wages than the US average ($50,400), with the highest wages for mature firms ($80,500).

We find that the employment growth in SC Traded Services has been concentrated in mature firms (figure 7.3a), which created 5.3 million net jobs between 1998 and 2015 and also experienced significant growth in wages. In contrast, our analysis suggests a significant decline in the employment created by new firms and young firms (−50 percent and −15 percent growth rates, respectively), with a job loss of 1 million. For total services, we find similar trends but less variance across firm types (figure 7.3b).

7.5 The Declining Presence of New Firms in Services

As figure 7.4 illustrates, the decline in startup employment in SC Traded Services is largely due to a 20 percent decline in new firm entry (from 97,000 in 1998 to 78,000 firms in 2015). There was a similar reduction in the rate of startup entry in total Services (−18 percent).

While several studies have examined the decline of startup activity in the US economy (e.g., Decker et al. 2014; Guzman and Stern 2019), no conclusive answer has been found as to the underlying causes. Some high-quality startups have grown fast and, in some cases, have been acquired by established competitors (Kim 2020). Acquisitions of young firms could perhaps explain some of the decline in the employment created by young firms.10

Despite the decline in the overall startup entry, SC Traded Services startups continue to play an important role in innovation and employment, accounting for a steady 19 percent of US startups during 1998–2015 period

10. We should recognize that the inflow of new establishments may be recorded in the LBD data with some delay, with census years being most accurate in recording new establishments.
In contrast, in 2015, new manufacturing firms accounted for only 3 percent of US startups. Assuming startups are an important source of innovation (Romer 1990), a significant share of new ideas and new firms therefore reside in the SC Services industries. Removing barriers to startups in this sector could play a vital role in policies to promote and diffuse innovation across the economy.

### 7.5.1 Company Examples: Potential Challenges Faced by SC Traded Services Startups

There are many examples of new and young firms in SC Traded Services in the US economy (e.g., DirectDefense, Tulip, ShipHawk, Symbia Logistics, and WP Engine). However, SC Traded Services firms, and startups in particular, face barriers that may limit their growth, particularly in access to skills and capital (Delgado and Mills 2021). To scale up, they must integrate their specialized service inputs in the value chain of business customers. For example, Tulip Interfaces produces an industrial app for the organization of work in manufacturing plants. To grow, they must create software that can be tailored to the needs of distinct customers, requiring access to capital, data, and nearby customers.

Another challenge is the protection of startup innovations from (big tech) competitors in the absence of intellectual property. Services are not patent intensive and can be easily copied or simultaneously developed by established firms with better access to complementary resources (e.g., data). For example, MIT startup Point API (previously called “EasyEmail”) launched

---

11. These examples are based on public databases (including Crunchbase), an interview with Mark Gillett at Silver Lake Partners, and a startup panel (including the founders of Tulip Interfaces and Point API) organized by the authors.
in 2016 with software to predict and autofill e-mail replies. Soon after their launch, Google announced a similar tool during its annual conference for software developers, which discouraged some Point API investors. The startup responded by positioning its software for customer support businesses, but it experienced difficulty in retaining users after Google released Smart Compose, and it closed operations by 2019.

7.6 Servicification of Manufacturing Incumbents

The employment growth in SC Traded Services has been concentrated in mature firms (figure 7.3). This raises the question of whether this growth is associated with manufacturing incumbents transforming into services, a phenomenon referred to as “servicification” in the economic literature (Low 2013) and “servitization” in the strategy literature (Vandermerwe and Rada 1988). Recent trade studies show an increasing servicification of manufacturing firms, which refers to the increased use of service inputs for the production of goods and increased sales of services (Lodefalk 2013, 2017; Low 2013; Timmer et al. 2014). In the strategy literature, there has been a growing interest in understanding the servitization of mature manufacturing firms—a process of adding revenue streams from selling services (Baines et al. 2017; Vandermerwe and Rada 1988; Visnjic Kastalli and Van Looy 2013). Relatedly, new information and communication technologies and management practices can facilitate the modularity and separation of research, development, design, and manufacturing (Fort 2017; Tripathy and Eppinger 2013), making service inputs more tradable domestically and globally.

We are interested in quantifying the servicification of manufacturing firms and determining whether this trend has resulted in net job creation. To quantify the transformation of manufacturing firms into services, we use a sample of about 2,000 incumbent manufacturing firms that have survived between 1998 and 2015. We condition on firms that in 1998 (our initial year) are mature (11+ age), large (500+ jobs), and have their primary industry in manufacturing. In 1998, these firms accounted for 5.6 million jobs, 33 percent of total manufacturing employment.

We find that there is a large servicification of manufacturing incumbents that occurs gradually and continuously during the examined period (figures 7.6–7.9). The aggregated employment of the manufacturing incumbent sample is used to compute the share of employment in Manufacturing versus SC Traded Services versus Other Services over time (figure 7.6). The share of employment in total Services increased by 13 percentage points

13. In these studies, service inputs are often classified as “intangibles,” and their contribution to the value added of final goods or services is poorly measured (Low 2013; Timmer et al. 2014).
Most of the growth is in the share of employment in SC Traded Services, which increased by 10 percentage points (18 percent to 28 percent).

The servicification of manufacturing incumbents is even more pronounced when we examine payroll, indicating that the jobs in services exhibit higher average wages (figure 7.7). The share of payroll in Services has increased by 17 percentage points (31 percent to 48 percent) and in SC Traded Services by 15 percentage points (26 percent to 41 percent).

This servicification took place through the destruction of many manufacturing jobs and the creation of fewer yet very high-wage jobs (figures 7.8...
and 7.9). From 1998 to 2015, these firms experienced a total job loss of 1.2 million but a payroll increase of $4.2 million. Manufacturing lost 1.7 million jobs and $80 million in payroll. In contrast, SC Traded Services gained 400,000 high-wage jobs, and payroll increased by $76 million (in 2015 USD).

Our results are not driven by a few “superstar” firms (Autor et al. 2020). The analysis suggests that many large manufacturing incumbents experienced servicification. We find that by the end of the period, about 20 percent of the firms have transformed into primarily SC Traded Service firms (i.e., the primary six-digit industry by employment is in SC Traded Services). Furthermore, we find similar servicification patterns for a large sample of small and medium manufacturing incumbents. To complement our empiri-
cal findings, we provide specific examples of manufacturing firms that have successfully evolved into SC Traded Services over the years.

7.6.1 Company Examples: The Continued Servicification of IBM and Intel

**IBM:** International Business Machines Corporation (IBM) was founded in 1896 as a punch-card data processing machine manufacturer. It found its footing as a hardware manufacturing company in the 1900s. Making all its components in-house, IBM became the leading computer company in the 1960s (Rothaermel et al. 2015). But with the emergence of Apple in 1976 and other competitors in the personal computer (PC) and related hardware space, IBM was forced to revise its strategy. Each change in top leadership has been associated with an increased focus on software and other services, particularly the bundling of these components together in an integrated sales offering.

When Louis Gerstner stood at the helm of IBM from 1993 to 2002, the company coined the term “e-business” in its marketing campaigns, highlighting the firm’s strategy and new focus on the Internet and its capabilities for businesses. In 2002, Sam Palmisano stepped into the CEO role, reorganizing IBM around three complementary segments: hardware, software, and services. His focus on the services component was undeniable. During his tenure, IBM sold its PC business to Lenovo and over a 4-year period, spent $11.8 billion to acquire numerous software and computer service firms (Rothaermel et al. 2015).

Virginia Rometty continued the journey into services when she became CEO in 2012. She told the *Wall Street Journal* in 2015 that “Hardware was the original soul of this company,” but “we can’t hold on to our past” (Langley 2015). In a speech to shareholders in 2016, Rometty highlighted the company’s transformation: “IBM . . . has reinvented itself through multiple technology eras and economic cycles . . . IBM is becoming much more than a ‘hardware, software, services’ company. We are emerging as a cognitive solutions and cloud platform company” (IBM 2016).

We used NETS data to quantify IBM’s servicification. The analysis shows that while IBM’s primary industry (6-digit NAICS) by employment in 1998 was *Electronic Computer Manufacturing*, it has transformed into a primarily SC Traded Service firm, with *Custom Computer Programming Services* as the primary industry in 2015. Specifically, the share of employment in SC Traded Services increased from 45 percent to 59 percent during 1998–2015. This transformation was accompanied by a large reduction of IBM’s manufacturing and service jobs in the US (the compound annual growth rate [CAGR] was −5 percent).

**Intel:** Founded in 1968, Intel Corporation made a name for itself as a semiconductor chip manufacturer. It created a general-purpose technology (GPT) and a whole industry—semiconductors—with the Intel 4004 micro-
The Servicification of the US Economy

The success of the PC in the 1980s led to the prime positioning of the company as the go-to supplier of chips for PC manufacturers like IBM. Intel excelled at continuously developing improved versions of its popular microprocessor chips—faster and with increased capabilities—but ran into a significant hurdle when adoption of new models slowed. To combat this lag in sales, the company rolled out a brilliant marketing and branding campaign centered on the now ubiquitous “Intel Inside” tagline and logo (Moon 2005).

Since those early days, Intel has maintained its dominance in manufacturing PC components, but as the company faced declining PC sales, it has diversified into components for other devices, software, and cloud computing. Using NETS data, we find that while the company’s primary industry remains in SC Manufacturing (Semiconductor and Related Device Manufacturing), it has continuously and rapidly increased its presence in SC Traded Services in the US economy (in particular in Custom Computer Programming Services). The percentage of firm employment in SC Traded Services increased from about 4 percent in 1998 to 26 percent by 2015, creating many service jobs (the CAGR was 8 percent). In 2016, Intel announced a significant restructuring effort, stating in a press release that the move was necessary to “accelerate its evolution from a PC company to one that powers the cloud and billions of smart, connected computing devices” (Intel 2016).

The servicification of this supply chain firm has been reflected in its branding and communication strategy. In January 2016, in a plan to expand beyond the extremely successful “Intel Inside” campaign, the company revamped its brand messaging: “Intel Inside makes amazing experiences outside.” Penny Baldwin, VP and GM of global brand management and reputation explained: “By putting the focus on Intel Inside, we’d gone brand invisible. . . . We’re trying to bring our brand from the inside to the outside. From being seen as a PC component to being an experiential exponent and an enabler of experience” (Schiff 2016).

7.7 The Growth of SC Traded Service Incumbents

Finally, we examine the role of large incumbent SC Traded Service firms (e.g., Microsoft) in the growth of this sector. Industries in SC Traded Services often have many layers of buyer industries, and therefore can themselves be important engines of innovation and growth. In fact, modern equivalents of GPTs like semiconductors reside increasingly in service or “digital” inputs, such as cloud computing and artificial intelligence (Brynjolfsson, Rock, and Syverson 2018; Cockburn, Henderson, and Stern 2018; Delgado and Mills 2020; Trajtenberg 2019).

For this analysis, we use a sample of about 1,000 incumbent SC Traded Service firms that survived from 1998 to 2015. These firms have the following attributes in our initial year (1998): they are mature (11+ age), large
(500+ jobs), and their primary industry is in SC Traded Services. Preliminary analysis shows that these firms experienced significantly high rates of net job creation during 1998–2015. Thus, while the job creation debate often focuses on manufacturing, the reality is that large service inputs firms have created many well-paying jobs. These firms play an important role in the servicification of the US economy.

7.7.1 Company Examples: Microsoft and Service Platforms

There is no shortage of incumbent service firms that have grown significantly during our time frame, capitalizing on the increasing use of data and the Internet, cloud computing, and AI technology. Examples range from high-growth enterprise software firms and consulting firms (e.g., Salesforce, Workday, SAP, and Red Ventures) to engineering and design service firms like Aecom and IDEO. Microsoft, a well-known incumbent services firm, illustrates the scalability of service inputs.

**Microsoft**: Founded in 1975, Microsoft was a software company from its outset, developing tools for the emerging PC industry. Microsoft Word was first released in 1983 and quickly took over the marketplace along with the Office suite of applications. Gawer and Cusumano (2002) demonstrated the importance of the Windows platform for the innovation capacity of many of Microsoft’s customers. Focusing heavily on Windows and Office, Microsoft covered the enterprise software market through licensing agreements up through the 2000s.

By 2013, however, “the sale of prepackaged operating systems and software on PCs” was declining. Consumers were interacting with technology in varied ways with the increasing adoption of smartphones, tablets, and other mobile devices. Responding to these trends, Microsoft reorganized itself as a “devices and services company” and later, under Satya Nadella’s leadership, as a company focused on a “mobile-first, cloud-first” strategy (Foley, Mayfield, and Boland 2017). The company developed its fast-growing cloud service, Microsoft Azure, and shifted to a constantly updating subscription model for Office 365. Related cloud-based products, such as Skype and SharePoint, have followed, as Microsoft continues to build out its software-as-a-service platform.

Our analysis (based on NETS data) illustrates the high scalability of this firm. During the entire period 1998–2015, over 90 percent of Microsoft’s employment was in SC Traded Services, mainly in *Software Publishing*. These services experienced fast growth in employment (CAGR of 6 percent).

7.8 Conclusion: How to Support Innovative Service Firms

The servicification of the US economy is a significant source of anxiety due to the loss of well-paying jobs in manufacturing. However, strong growth in SC Traded Services businesses provides an important source of new, high-wage jobs (many of which require STEM skills). This raises
important questions, particularly concerning policy initiatives that might support more of these businesses and create innovative service jobs.

One puzzling finding of our study is the decline in the number of entrepreneurial firms in SC Traded Services. While young firms in this sector continue to represent a large share of the overall entrepreneurial activity in the US economy, their decline raises questions regarding the missing startups in this increasingly important services sector. What are the barriers that stifle the entry and growth of entrepreneurial firms in high-tech services? Given the outsized role of startups in generating technological innovations and growth (e.g., Romer 1990), future research is needed to advance our understanding of the sources and solutions to these barriers. In particular, barriers related to access to STEM skills, capital, buyers, and data, as well as the ability to protect innovations, should be examined (Delgado and Mills 2021).

Another key finding in this study is that job creation in SC Traded Services is driven primarily by mature firms: the transformation of incumbent manufacturing firms into services and, especially, the growth of incumbent service firms. This pattern raises new questions about how incumbent firms are able to successfully transform from manufacturing into product-service or pure service firms. This transformation may be associated with firms moving manufacturing activities overseas (Fuchs et al., chapter 1 in this book) while choosing to produce innovative services in the US. The servicification of incumbent firms can generally occur by either organically developing their capabilities in-house (e.g., retraining their workers) or externally sourcing the necessary technology and skills. Organically, firms may train their workers with new skills that enable an effective response to the evolving competitive environment. Externally, firms may partner with—or acquire—other firms as a way to outsource new technology and talent. Relative to organic growth, how might an acquisition-based approach shape the incumbents’ long-run innovation and growth? And what is the role of industry clusters and specialized STEM skills in the growth of these innovative services across regions (Delgado and Porter 2017; Eckert, Ganapati, and Walsh 2019)?

We conclude by discussing the prospects of SC Traded Services. We point to two directions. First, in terms of the overall size, we expect that this sector will continue to grow in both absolute and relative size. Especially with the global COVID-19 pandemic accelerating the economic trend toward digitization, the rising importance of data-driven services that rely on AI and Internet technologies (see e.g., Jones and Tonetti 2020; Mills 2019; Trajtenberg 2019) will likely catalyze further growth in many areas of SC Traded Services, such as cloud computing, financial technology, logistics, and health care. Second, in terms of the composition of firms, we expect that incumbents will continue to outpace the startups in this sector unless barriers to accessing data and other critical resources are addressed. Consistent with this view, a concurrent trend is the rise of superstar firms, which are industry giants with disproportionately high market shares (Autor
et al. 2020). Another supporting trend is the growing prevalence of startup acquisitions in many industries (e.g., Kim 2020), which may further tilt the competitive landscape toward incumbent firms. A natural consequence of a startup acquisition is the transfer of market power from entrepreneurial firms to the acquiring incumbents before ventures can sufficiently mature and reach their innovation and size potential. As a result, young firms may play a declining role in driving jobs in SC Traded Services.

Overall, creating an appropriate business environment for new and young firms to overcome barriers to entry and growth, and for incumbent firms to adapt to changing trends, is essential to encourage growth in Supply Chain Services and innovation in the US economy.

Heterogeneity in the Great Sectoral Shift

The heart of US economic activity has broadly shifted away from manufacturing physical goods toward services over the past 70 years. While
