Chapter pages in book: (p. 69-93)

## CHAPTER 5

## Wages by Industry and Region

## Wages by Industry

The daily wages paid by the various manufacturing industries differed substantially. Among the 18 industries from the Weeks Report, the highest-wage industry paid double the lowest in 1860

[^1]and almost double in 1880 (Table 22); ${ }^{1}$ the range for the middle half of the distribution was 50 cents per day in 1860 and 70 cents in 1880 . Among the 13 manufacturing industries from the Aldrich Report, the highest-wage industry paid almost double the lowest in 1860, slightly more than double in 1880, and somewhat more than double in 1890 (Table 23). In both sets the lowest-paying tended throughout to be cotton goods; but the highest-paying varied: in the Weeks data, it was foundries in 1860, tin and sheet iron in 1870, and saw and planing mills in 1880; in the Aldrich data it was stone in 1860, 1870, and 1890, carriages and wagons in 1880.

Some check on these results can be had from the decennial census of manufacturing, which reports the number of employees and total wages during the years ended May 31, 1860, 1870, 1880, and 1890, by selecting 17 industries most nearly the same as those analyzed from the Weeks Report (Table 24). Average annual earnings per worker have been computed for approximately comparable industry classifications in each decennial year. Such averages depend on the accuracy of the census enumerations and industry classifications (firms turning out more than one kind of product are classified on the basis of their principal product). They are also subject to fluctuations from industry to industry and over time-because of changes in the distribution of employed among the different wage categories and variations in the days worked by the average earner during the year. Considerable disparity might well be expected, therefore, between the industry behavior of Weeks-Aldrich daily wages and of census annual earnings. On the other hand, the census undertook to reach every establishment of more than negligible size in each industry, and if the pattern was reasonably similar to that of the wage data, this would be a heartening indication that our small samples of Weeks-Aldrich firms have some value. Census data have the advantage, moreover, of covering decennially the full period 1860-90.

The earnings differentials shown by the census were slightly greater-the highest earnings having been a little more than double the lowest during 1860-80, and a little less than triple in 1890. On the whole, the high-wage industries had high annual earnings, and the low-wage industries low earnings. But the rankings were a long way from being exactly the same. For example, saw and planing mills and flour and grist mills were fairly high in wage rates but

somewhat lower in annual earnings, presumably because of fewer days worked during the year.

Industries with above-average wage levels in 1860 tended to increase less than the average. Of the nine Weeks-reported industries with above-median daily wages in 1860, six had smaller-than-median increases by 1880 . Of the six Aldrich-reported industries with abovemedian wages in 1860, five had below-median wage increases by 1880 and four by 1890 . So also with census annual earnings (Tables 22-24). These tendencies support Mitchell's findings for 1860-80: "All of the time, the highest group [males earning $\$ 2.50$ or more] had the lowest relative wages." ${ }^{2}$

Nevertheless, there was no significant tendency for wage or earnings differentials to widen or narrow over the twenty- or thirtyyear period. In general, the high-wage and -earnings industries of 1860 were also the high-wage and -earnings industries in 1880 and 1890, despite the fact that several industries shifted position rather distinctly. Three Aldrich Report industries had identical ranks in 1860 and 1890 (stone, 1 ; books and newspapers, 8 ; cotton goods, 13); three others changed one place in rank (metals, paper, and woolen goods); two others changed two or three places. Seven of the Weeks Report industries occupied the same rank in 1880 as in 1860 (hardware, tanneries, iron blast furnaces, paper, brickmaking, woolen goods, cotton goods); five others changed one to three places. Three census-reported industries held the same earnings rank in 1860 and 1890 (distilled liquors, 6 ; brick and tile, 16 ; and chewing tobacco, 17); four changed rank by one place; eight others changed rank three places or less.

Moreover, all of the three sources indicate a fairly stable average deviation of wages among industries-about 20 percent of the mean. The Aldrich and census data show a slight rise in deviation from 1860 to 1890, the Weeks data a slight decline from 1860 to 1880 , both changes too small to suggest significant trends in inter-industry wage differentials for the industries and periods covered. ${ }^{3}$

Some industries may be primarily in high- or low-wage areas, or may be dominated by high- or low-paid occupations. Have these differences been the cause of inter-industry differentials? The effects of geographical and occupational composition will be examined later; we test here whether indụstry differentials persist within the same regions and occupations.

[^3]One test is to compare average deviations of daily wages among ten industries from the Weeks Report for the East and West. If industry differentials are partly due to geographical location, the dispersion should be smaller for the same industries within the East or the West, than within the United States as a whole. But nothing like this is observable in Table 25. In 1860 the relative average

TABLE 25
Average Deviation of Daily Wages among Ten Industries Having Data Separately for East and West; Weeks Report, 1860 and 1880

[^4]deviation was slightly smaller in the East and West than in the nation as a whole; but in 1880 it was somewhat larger, and the ratios of highest- to lowest-wage industry were even a bit higher in the West than in the United States for the same industries.

A second test is to compute the same deviation of annual earnings among industries with census data for five major regions of the United States: New England, Middle Atlantic including Delaware and Maryland, Central states including Kentucky, the South, and Pacific Coast states (Table 26). Again, the within-region deviations were, if anything, higher than those within the United States as a whole. The differences were not great; for most regions and for the United States, the inter-industry deviations were roughly 20 percent; though for the South and Far West, they were 25 to 31 percent. The ratio of the highest- to lowest-earnings industries also tended to be larger in the separate regions. The paradoxically greater deviations within the regions are undoubtedly due to the greater element of

randomness among a smaller number of establishments and workers. In any case, regional location does not seem to be an important source of inter-industry wage differentials.

Were inter-industry differentials traceable to occupational composition? Data of the First Annual Report for 1885 have been classified into hourly wage rates of teamsters in 27 industries, carpenters in 22 industries, and so on, for seven occupations occurring in eight or more industries (Table 27). The report offers enough wage data by occupation, industry, and area, to minimize the element of randomness arising out of differences in the wage practices of different establishments.

The average deviation for the same occupations occurring in different industries ranged from 17 percent for teamsters to 8 percent for patternmakers, with a mean of about 12 percent for the seven occupations-compared with 20 percent for the average deviation among the 37 industries computed without regard to occupational composition. Similar results were found for occupations and industries located in a single state-New York, where observations were obtainable for a substantial number of industries.

What part of the wage increase during 1860-90 was due to increase in wages within industries, and what part to the shift of workers from low-wage to high-wage industries? The answer can be given only from wage data that represent a substantial cross section of the nation's employment. This, the Weeks-Bulletin 18 data and the Aldrich data do not individually provide. In the former, the changing composition of employment had a slight lifting effect on average wages (at least for 1890) and in the latter a substantial depressing effect. A more reliable indication is supplied by the annual earnings data for 17 selected industries, which employed over 40 percent of the nation's factory production workers throughout the period. These data suggest that about one-fifth of the rise in average annual earnings was due to the shift of employment from lower- to higherearnings industries (Table 28).

The relatively expanding industries were mainly those producing hard goods-durable consumer and producers' products. It was the hard goods industries that were mainly the high-wage and highearnings industries in both 1860 and 1890, and their aggregate share grew from less than half to more than two-thirds of the total

The employment weights were employment as reported by the censuses of manufactures for those states from which wage data were reported. For all states in which wage data were reported for any industry, requisite employment data by industry were available. In the Aldrich wage data, only New England and the Middle Atlantic states plus Maryland and Ohio were represented. In the census annual earnings data, all states were represented both in the earnings and the employment weights.
${ }^{\text {a }}$ Data by industry in the Weeks Report cover only 1860-80. The wage index for 1880-90 had to be extended by means of wages in ten manufacturing occupations reported from twelve large cities by the Department of Labor in its Bulletin 18. These wage data were weighted by occupational employment data for the states in which the cities were located, from the censuses of manufactures. In this table in 1890 wages were weighted by the occupational distribution of employment in 1880 . The index of change from 1880 to 1890 was then linked to the index of change from 1860 to 1880.
employed by the 17 industries. All of the eight hard goods industries, except iron and steel blast furnaces, expanded their shares of employment; all of the nine soft goods industries, except malt liquors and cigars and cigarettes, contracted their shares. The biggest relative expansion of employment occurred for the high-wage basic metals and metal products; the biggest relative contraction for the low-wage cotton and woolen textiles.

Other data might yield other results, but we conclude from this section: that substantial wage variation did exist among different
industries, the highest-wage industry having paid roughly double the lowest, and the average deviation in wage rates among the different industries having been roughly 20 percent of the mean wage; that this variation was not due to regional location of the various industries; that perhaps a third of it could have been due to differences in occupation-mix; that the rankings of industries in the national wage or earnings scale tended to maintain themselves fairly well throughout the thirty years, with a few instances, however, of an industry drastically altering its pay scale relative to other industries; and that there was no significant tendency for the wage dispersion among industries either to widen or to narrow over the three decades; and finally that about one-fifth of the rise in wages and earnings may have been due to the relative shift of workers from the low-wage soft goods industries-especially textiles-to the high-wage hard goods industries-especially basic metals and metal products.

## Wages by Region

The regional structure of wages is most effectively analyzed by industries and occupations.

TABLE 29
Weighted Average Daily Wage-Rates in Manufacturing Industries for the East, West, and South; Weeks Report, 1860-1880

| West | 1.74 | 2.39 | 2.42 | 2.32 | 2.30 |
| South | 0.99 | 1.07 | 1.07 | 1.15 | 1.17 |
| percentage of wages in the east |  |  |  |  |  |
| West | 141 | 139 | 132 | 130 | 137 |
| South | 80 | 62 | 58 | 65 | 70 |

For explanation, see Appendix Table A-3.
Differentials in daily wages by industry over time may be computed from data of the Weeks Report, covering three major regions (Table 29). Inter-regional differences were substantial-with wage levels highest in the West, intermediate in the East, and lowest in the South. The alignments persisted over the twenty years to 1880 , but southern and western wages rose less rapidly, so that southern
wages fell relatively further below eastern wages, and western wages may have fallen somewhat toward eastern wages.
The 18 industries in the Week Report are not all represented in each region. What are the results if we compare only industries with representation in both East and West or East and South?

Ten industries offer wage data for both East and West; though the number of establishments in one or the other region is usually very small, and even in the same industry firms may produce somewhat different products in different regions.

TABLE 30
Percentage Ratio of Daily Wages in Western and Southern Establishments to Those in Eastern Establishments; Identical Industries, Weeks Report, 1860-1880

For explanation, see Appendix Table A-3.
The wage differentials varied widely among these industries (Table 30). Wages were higher in the West for most industries in most years, but the pattern was mixed. The ratio of western to eastern wages ranged in 1860 from as high as 2.40 for clothing to 0.84 for saw mills. In four industries wages were consistently higher in the West than in the East throughout 1860-80, but in the remaining six,
they were often lower-consistently lower in paper and lower in all but one or two quinquennial dates in foundries and furniture. The median of the ten industries indicates a slight rise in the ratio of western to eastern wages, though the entire change occurred during the Civil War years, and no significant trend was observable after 1865.

Only three industries had establishments in the South, but each provided wage comparisons in all three regions. These were cigars and tobacco, paper, and saw and planing mills. In all three, wages were consistently lower in the South, and in two-cigars and tobacco and saw and planing mills-lower relative to the West than to the East. Wages in the South were further below the other two regions in 1880 than in 1860, but almost the entire widening occurred between the quinquennial years 1860 and 1865; thereafter the South-East differential remained roughly constant. It would appear from our very small sample that wages tended to be lower in the East than in the West and still lower in the South, and that these differentials tended to widen during the Civil War, but not between the end of the Civil War and 1880.

Thus far, the regional wage comparisons cover only 1860-80. For $1880-90$, we have two separate surveys covering large numbers of workers and establishments: the First Annual Report of the Commissioner of Labor for 1885 and the Dewey-Census Report for $1890 .{ }^{4}$

For 1885 daily wages were higher in the West and lower in the South, than in the East; but the differences were much smaller than those indicated by the Weeks Report for the earlier years: the First Annual Report shows western wages to have been 6 percent above eastern in thirteen industries with establishments in both regions, and southern wages 19 percent below eastern in five industries (Table 31). In 1890, the Dewey Report on hourly wages indicated still smaller differentials-whether for industries common to those in the First Annual Report or for a mixed list. Southern establishments paid wages equal to or higher than eastern in three industries. Only 7 out of 15 industries paid higher wages in the West than in the East.

Are we to conclude that the regional wage differentials were very high and unchanging in the years up to and including 1880, but then fell very sharply in 1885 and again, mildly, in 1890 ? Such a conclusion would surely be unsafe.

The Weeks Report had the virtue of enabling us to compare wages

[^5]
## WAGES BY INDUSTRY AND REGION

for the same firms, occupations, and industries over time, but it was restricted to a small number of establishments. This small sample has several pitfalls. First, wages may vary widely among establishments within the same industry. Second, industries are broad classifications; a manufacturer of tobacco products in one region may produce plug tobacco, in another mainly fine-cut. Third, the occupations with wage data varied from one establishment to another as from accidents of record-keeping. The First Annual and the Dewey Reports, covering hundreds of establishments and

TABLE 31
Percentage Ratio of Wages in Manufacturing Industries in Southern and Western States to Those in Eastern States, 1885 and 1890; First Annual and Dewey Reports
$\left.\begin{array}{lcc}\hline \hline & \begin{array}{c}\text { First Annual } \\ \text { Report, } \\ \text { Daily Wages }\end{array} & \begin{array}{c}\text { Dewey Report, } \\ \text { Hourly Wages }\end{array} \\ & 1885 & 1890 \\ \text { WESTERN wages in PERCENT OF EASTERN }\end{array}\right]$

[^6]more than a hundred thousand workers, are less subject to the kind of variation that occurs if an abnormally high- or low-wage firm happens to represent an industry in a state or region. But all that these various data entitle us to say is, that wages in most industries were probably higher in the West and lower in the South than in the East throughout 1860-90, with the differentials varying among industries and over time, but with no net trend apparent.

This regional behavior of wage rates was broadly confirmed by average annual earnings (Table 32). Compared with the Middle Atlantic states, earnings were about the same in the Central (Middle West) states, 10-30 percent lower in the South, and much higher in the Pacific states. Again, the differentials varied widely among industries, with several having higher earnings in the South than in the Middle Atlantic states in certain years though only in the cigar and cigarette industry was this true in both initial and terminal years. ${ }^{5}$

Annual earnings are the only data which cover the whole nation for the entire period. In all the regions outside the Middle Atlantic, earnings tended to decline in relation to those in the Middle Atlantic, the decline being substantial in the South and enormous in the Far West (where earnings in 1860 had been extremely high). Some industries moved counter to this relative trend in all regions but in the great majority of industries earnings moved down compared with the East. For the United States as a whole, only saw mills had absolute earnings that were not higher in 1890 than in 1860. In the South, flour and grist mills, paper, and chewing tobacco had lower earnings in 1890; but eleven of the twelve Pacific Coast industries paid lower absolute dollar earnings in 1890 than thirty years before.

These declines in relative and even in absolute earnings outside the Middle Atlantic region brought the average annual earnings for New England, the Central West, and the Pacific Coast closer to those for the Middle Atlantic; but the decline for the South depressed its earnings relatively further below eastern earnings in 1890. The net effect may have been that average annual earnings showed, in general, less interstate dispersion in 1890 than in 1860 (Table 33). Thirteen industries manifested declines in relative average deviations among states, and the median declined from 21 to 17 percent. The decline, however, occurred in the last decade; most of the industries had a higher dispersion in 1880 than in 1860. Thus the census earnings confirm the Weeks wages, in showing an increase in

[^8]geographical dispersion of earnings by 1880, in the face of a net decrease between 1860 and 1890. In addition to a net decline in the interstate dispersion of earnings within the United States as a whole, there were also net declines within the southern, central, and Pacific regions where the states seemed to be somewhat closer, in their average earnings, in 1890 than in 1860.

Regional disparities in wages and earnings have been analyzed by industry. But the same industry may conceivably employ different combinations of occupations in different regions; say, more unskilled workers in the South and more skilled workers in the East. We now compare wages and earnings in different states and regions for the same occupation.

First we analyze the occupational wages between 1870 and 1890 reported by the Department of Labor in its Bulletin 18. This report gathered daily wages for ten occupations more or less identifiable with manufacturing, though found in other industries, and four occupations identifiable with the building trades, also found in other industries. All except laborers were skilled and all were from large cities-two in the South, five each in the East and West. None of the occupational wages were identified by establishments, but the continuity of the quotations suggests that the same occupations were reporting from one year to the next. The number of establishments was probably small.
For "manufacturing" occupations, wage rates tended actually to be higher in southern than in eastern or western cities (Table 34). Median wages for the manufacturing occupations were higher in the two southern cities than in the East and West in 1870, 1875, and 1880, and were lower only in 1885 and 1890. Wages were higher in all quinquennial years for boilermakers, cabinetmakers, and iron molders; in several quinquennial years, for compositors and stonecutters; in 1875 and 1880, even for the unskilled category laborers. For building occupations, however, southern wages were below the other regions by 10 to 20 percent in all quinquennial years.
The comparison between eastern and western wages was similarly mixed. In the manufacturing occupations, wages tended to average a few percent higher in the West (as we have already discovered from our industry data). But in two of the four building occupations, they were lower in the West. Again, in both South and West daily wages tended to decline relatively to those in the East. Wages were relatively lower in 1890 than in 1870 in seven of the ten manufacturing occupations and in three of the four building occupations; in several remaining occupations the rise was either inappreciable or nonexistent.

We have compared regional differentials of industry wages without regard to occupations and regional differentials of occupational wages without regard to industry. We now compare regional wage differentials for the same occupations in the same industries, relying on the First Annual Report for 1885 and the Dewey Report for 1890.

| Median percentage | 87 | 90 | 84 | 81 | 76 | 94 | 103 | 98 | 95 | 94 |

For explanation, see Appendix Table A-4.
For 1885 we examine wages in selected occupations in cotton goods, woolen goods, and metal industries-using those occupations and industries with wages of substantial numbers of workers and establishments recorded in at least three major regions (Table 35). Southern establishments paid lower wages than Middle Atlantic establishments in every one of the cotton-goods and woolen-goods occupations and in five of the seven metals occupations. Again the differentials varied widely. Compared to the Middle Atlantic, southern wages ranged in cotton goods from 51 percent for teamsters to 94 percent for male weavers, in woolen goods from 35 percent for
loom fixers to 68 percent for mule spinners, and in metals from 75 percent for teamsters to 121 percent for machinists.

The above comparisons are for occupations without regard to age or sex of the workers. However, since most occupations are engaged in more or less exclusively by workers of the same sex, this limitation is not serious. Nevertheless we can check our results by comparing adult-male wages in certain occupations in different regions (Table 36). In 1885, adult males invariably received lower wages in the South than in the East or West, and the same may be

For explanation, see Chapter 2 above.
said for adult females. Weavers in cotton goods and packers in tobacco offer separate comparisons for males and females; in each the southern wages were below eastern wages. Western wages were below the East for three of the five metal-goods occupations, for male and female weavers in woolen goods, and for female tobacco

packers; but western wages were above eastern in the three male tobacco occupations.

For 1890 similar regional comparisons are available for homogeneous occupations and industries, but we confine this comparison entirely to males 16 and older (Table 37). Again southern wages were lower in most occupations, notably so in cotton goods, metal working, glass, and clothing. Exceptions were foremen, machine hands, and machinists in iron and steel mills, laborers in printing and lumber, and cigar makers. Wages were generally less unfavorable in the South for skilled occupations, but there were exceptions: printing foremen received 5 percent less in the South than in the Middle Atlantic, printing laborers about the same in both regions. ${ }^{6}$ New England wages were generally mixed in relation to the Middle Atlantic, so that it would be hard to tell which were typically higher or lower.

For 1885 average deviation of wages among states was further computed for identical occupations in the same industries (Table 38). The deviations tended to be less than those in Table 33 for cotton goods and woolens, and more for metals, but on the whole the differences were not very significant. Narrowing the regional and interstate comparisons to the same occupations within the same

industry yielded results not significantly different from those computed for the industries without regard to occupational composition.

Were the wage differences between regions greater than those between states within the same region? Observing the cotton-goods occupations for 1885 (Table 38), we find that so far as South-East differentials are concerned, this was definitely so. For example, in the case of carpenters in the cotton-goods industry, the percentage difference in average hourly wages between the South and Middle Atlantic was several times the average percentage deviation among states within the Middle Atlantic and southern regions. There were exceptions-notably male weavers-but in general the greater wage differences between South and East seemed to hold for all occupations of the industry. Only cotton goods, however, offered wage data for a sufficient number of southern states to make such a comparison possible.

[^10]
[^0]:    For explanation, see Appendix Table A-3.

[^1]:    ${ }^{\mathrm{D}}$ Computed from simple mean.
    ${ }^{\text {a }}$ In the case of the relative wages the median was computed

[^2]:    ${ }^{1}$ Gerhard Bry has objected to my use of the ratio of highest to lowest wage on the ground that it is unstable. I have retained it because of its simplicity and because it does not appear to be very unstable in this study. However, I have not placed undue weight upon it in my analysis of wage behavior.

[^3]:    ${ }^{2}$ Gold, Prices, and Wages, p. 167.
    ${ }^{3}$ The relative interquartile range was the same in 1880 as in 1860 in the Weeks and the census data. In the census data it shows a considerable drop from 1880 to 1890 ; in the Aldrich data, a small drop from 1860 to 1890.

[^4]:    The industries were carriages and wagons, cigars and tobacco, clothing, furniture, iron blast furnaces, machinery, paper, saw and planing mills, stove foundries, and woolens; see Appendix Table A-3.
    ${ }^{a}$ Computed from the simple mean.

[^5]:    ${ }^{4}$ The Dewey Report was actually made in connection with the 1900 census, but the establishments were asked to report their wages for 1890 also.

[^6]:    For explanation, see Chapter 2 and Appendix Tables A-7 and A-8.
    ${ }^{a}$ In addition to the above eight industries: boots and shoes 107 percent, liquors and beverages 133, machines and machinery 122, tobacco 84, brick 109.
    ${ }^{\circ}$ In addition to the above eight: clothing 207, cotton goods 98 , breweries 80 , iron and steel 107, flour mills 116, furniture 83, printing 73.
    c In addition to the above three: tobacco 58, and lumber 107.
    ${ }^{\text {a }}$ In addition to the above three: clothing 99, glass 127 , leather 79, breweries 93 , lumber 80 , foundries and metal working 100 , flour mills 50 , furniture 55 , printing 67.

[^7]:    ${ }^{5}$ R. A. Lester has found that the North-South wage differential varied widely in recent years. "A Range Theory of Wage Differentials," Industrial and Labor Relations Review, July 1952, p. 484.

[^8]:    Source: Censuses of Manufactures, 1860-1890; see also $\quad \begin{gathered}\text { a Maryland, Delaware, and West Virginia included in the } \\ \text { Appendix Table A-9. }\end{gathered}$ Middle Atlantic region; Kentucky in the Central region. Appendix Table A-9.

[^9]:    ${ }^{6}$ Compare with the findings of Harry Ober, "Occupational Wage Differentials, 1907-1947" Monthly Labor Review, August 1948, p. 129.

[^10]:    Hourly earnings by state, region, industry, and occupation, computed by the National Bureau of Economic Research; average deviation computed in this study. Only those occupations and industries were used here for which there were data for seven or more states.
    ${ }^{\text {a }}$ Number of states for which the National Bureau computed average hourly wage data by industry, occupation, and states.
    ${ }^{b}$ Computed by subtracting the average hourly wage for all workers and firms reported in that industry and occupation for each state, from the average for the same industry and occupation in that region, then adding these differences without regard to sign, and dividing by the number of states for which wage quotations were available. This yielded the average deviation in cents per hour, which was then expressed as a percentage of the average hourly wage for that region.
    c Computed by taking the difference between the average hourly wages of the two regions and dividing by the average for the two regions.
    d Includes Maryland, Delaware, and West Virginia.
    e Excludes the above three states and Texas.
    ${ }^{\text {P }}$ Includes Kentucky.
