## A. INTRODUCTION

The data used in this portion of the report were taken from the flow of funds accounts wherever possible. ${ }^{1}$ In three areas, however, we found it necessary to supplement the flow of funds estimates. First, the published accounts contain no data on the value of tangible assets; we incorporated such estimates as were available from the Office of Business Economics and developed our own series for housing and for public sector tangibles. The data are given in Tables IA-1 through IA-7.

Second, there are several financial institutions which are not shown explicitly in the flow of funds accounts; instead they are included in other sectors, particularly in the household sector. In the interest both of measuring more accurately the financial position of true households and of being able to study the behavior of these institutions which are important participants in the securities market, we created time series for them. These estimates are shown in Tables IA-8 through IA-18.

Third, the focus of the Institutional Investors Study on the market for corporate securities made us reexamine the flow of funds estimates of the amounts outstanding of, and transactions in, such securities. In the case of corporate shares, the market value outstanding series in the flow of

[^0]funds was replaced by that developed in Appendix VI ${ }^{2}$ although the flow of funds net issue series was retained. In the case of corporate bonds, both the stock and the flow series were replaced by series which, although still based on par values, at least have the virtue of allowing households to hold nonnegative amounts of such securities, a characteristic not shared by their predecessors. These data are given in Tables IA-19 through IA-22.

Finally, these new estimates are combined with the flow of funds estimates of financial assets and liabilities to produce the sector balance sheets shown in Tables IB-1 through IB-9 for selected years. ${ }^{3}$

## B. ESTIMATES OF TANGIBLE ASSETS

## 1. Land

The land estimates used in this appendix are those given in Milgram's Appendix II with a few exceptions. The land of financial corporations was estimated by multiplying the Internal Revenue Service estimates of the book value of land of all financial institutions by the market-to-book ratio developed in Appendix II for "finance, insurance, and real estate." No adjustment was made for unincorporated financial institutions. These tend to be brokerage houses; and the land holdings of the finance, insurance, and real estate aggregate for partnerships and proprietorships are accounted for primarily by the holdings of real estate firms.

The estimated value of farm land used here differs from that reported in Appendix II. Although both estimates were made by subtracting the value of buildings from the U.S. Department of Agriculture's estimate of the value of farm real estate, Appendix II used the USDA's estimates of structures, while we used the estimates described below.

Transactions were measured by first differences in the holdings, since the net purchase data of Appendix II were rather spotty.

## 2. Reproducible Tangible Assets

All the estimates of depreciable assets reported here were made using the perpetual inventory method. This method involves the computation of a weighted moving sum of annual data on gross investment in the asset in question; the weights are determined by the particular life and depreciation assumptions employed in the calculation. The difference between the gross investment of a given year and the change in the stock

[^1]during that year is by definition the depreciation which has occurred. To derive the replacement cost estimates used in this report, the calculation is first made in terms of constant dollars, and then the stock and depreciation estimates are reflated to current year prices.
The gross investment series used for the estimates of the private stock of depreciable assets are in all cases those used in the gross investment component of the income and product accounts produced by the Office of Business Economics at the Department of Commerce. In the case of public sector estimates, the construction data and equipment series were taken from the income and product accounts wherever possible; data are regularly published, although the two government sectors are not credited with capital formation in the OBE's accounts.
a. Private Nonresidential Structures and Equipment. Stocks of plant and equipment for the private sector were obtained from the OBE's Capital Stock Study; the variant used was straight-line depreciation at Bulletin F lives. ${ }^{4}$ This concept was selected both for comparability with the earlier NBER estimates and because there is some presumption that in their own internal decision making, at least, firms use a much less rapid write-off of their plant and equipment than they demand for tax purposes. A theoretically preferable present-value measure of the stock of capital was not available. To calculate such a measure would have necessitated the specification of a discount rate parameter in addition to the life estimate; furthermore, the OBE estimates embodied much more refined adjustments for the retirement distribution and for asset categories than we could have readily duplicated in calculations using the present-value method.

The flow of funds estimates of corporate and noncorporate investment in plant and equipment are obtained from the OBE. Such estimates were also used by Allan Young in his study of depreciation and corporate profits, which yielded stock estimates by legal form as a by-product. ${ }^{6}$ Although the data used in the Young study have not been kept up to date by the OBE, we did attempt to incorporate the statistical revisions necessary to make the components consistent with revised total stock and investment series. These series embodied both ordinary statistical revisions and the adjustments in the estimates of assets transferred between the

[^2]public and private sectors necessitated by a shift from sales price to original cost valuation. ${ }^{6}$
Ordinary statistical revisions were assumed to keep relative shares the same as they were in the Young study. The valuation adjustment for assets transferred between public and private ownership was assumed to be 95 per cent corporate for manufacturing equipment and structures, 90 percent corporate for nonmanufacturing equipment, and 100 percent corporate for nonmanufacturing structures.

Institutional structures were defined to be OBE's "institutional structures" plus one-third of the estimated stock of (or investment in) "social and recreational structures." Institutional investment in equipment was estimated residually by subtracting the construction estimates from the flow of funds series on "nonprofit plant and equipment" expenditures; it was assumed to account for a share in the stock of "nonfarm noncorporate manufacturing equipment" (as well as in the depreciation on that stock) equal to its share in the comparable gross investment estimates.

Estimates for farm nonresidential structures and equipment were taken directly from the OBE. Nonfarm noncorporate plant and equipment were the residuals after subtracting corporate farm and institutional plant and equipment from the total privately owned, incorporating the valuation adjustment on assets transferred from public to private ownership.

The subdivision of corporate investment into its financial corporate and nonfinancial corporate subsectors was largely a judgmental procedure. We assumed that in 1948 the investment of financial corporations was split equally between structures and equipment, and that the share allocated to structures steadily increased during the subsequent years, accounting for 55 percent of the total in 1952 and 72 percent of the total by 1968. (This assumption was based largely on the observed rapid growth in investment in structures by life insurance companies.) The annual percentages were then applied to the flow of funds estimates of financial corporate investment in plant and equipment, to obtain the structures and equipment components separately. Nonfinancial corporate investment in -structures and equipment are the residuals. These were then depreciated at rates of 2 percent for structures and 8.3 percent for equipment, assuming a 50 -year life for structures and a 12 -year life for equipment.
b. Private Residual Structures. The basic investment series are again taken from the national income and product accounts as given in the flow of

[^3]funds accounts. Since OBE estimates of the stock of housing were not available at the time at which this report was written, the investment series were depreciated exponentially in order to estimate the net stocks and associated depreciation series.
For 1-4 family nonfarm housing a depreciation rate of 2.0 percent was used; for multifamily housing a rate of 2.4 percent was employed, and for farm housing a depreciation rate of 1 percent was applied. Initial stocks for the end of 1949 were selected from the estimates developed in earlier work by one of the authors. ${ }^{7}$ The criterion used in selecting the initial stock and the depreciation rate were first, the consistency with the results of the 1950 Census of Housing, and second, whether its computational assumptions in combination with the gross investment series described above yielded housing stocks consistent with the 1960 Census of Housing. ${ }^{8}$

The stock of multifamily dwellings by sector was based on the flow of funds allocation of such investment between corporate and noncorporate purchasers. The 1949 stock was allocated between the two sectors in the same proportion as in an earlier NBER study. ${ }^{9}$

## c. Public Sector Structures

(1) Introduction. In order to arrive at a total stock figure for public structures by means of a perpetual inventory computation, we need an expenditure estimate and a price index for each year as far back as required by the service life assumption. Our two major categories are federal construction and state and local construction. Each of these is divided into several subcategories, which are listed below.

Federal
Residential
Nonresidential

State and Local<br>Residential<br>Nonresidential

[^4]Federal (cont.)
Highway
Conservation and development Military
Other

State and Local (cont.)
Highway
Conservation and development
Public service enterprises
Sewer and water
Other

The state and local government expenditures include federally aided expenditures. All calculations assume declining balance depreciation. The average service life assumptions are: 50 years for federal civilian and state and local residential structures; 50 years for nonresidential buildings; 30 years for highways; 80 years for conservation and development; 50 years for other federal nonresidential structures; 67 years for sewer and water systems; 50 years for public service enterprises; and 50 years for other state and local nonresidential structures.
(2) Estimates for 1946-68. Data on both federal and state and local government expenditures on structures during this time period were taken from unpublished Commerce Department data. There were only two departures from the OBE worksheets. Federal nonresidential expenditures in our system were a combination of their "nonresidential" and "industrial" expenditures. Also, the average of the price indexes of these two categories gave the price index used in our calculations for the overall category, nonresidential.

For state and local governments, between 1963 and 1968, the separation of "other," "sewer and water systems," and "public service enterprises" disappears. In order to compute the stocks, we had to have separate expenditure figures for these years. These were obtained by totaling the three categories for each year over the previous five-year period, and computing the percent share of each in the total. The percentages remained reasonably consistent (within 5 percentage points over this time period), so we extrapolated forward, using the mean percent of the 1958-63 total for each category, i.e.,

|  | Percent |
| :--- | :---: |
| Sewer and water systems | 9.2 |
| Public service enterprises | 67.2 |
| Other | 23.6 |

(3) Estimates for 1915-46. All figures for expenditures were taken from Construction Volume and Costs, 1915-1956 (page 10), a statistical supplement to Construction Review, by the departments of Commerce and Labor.

The price indexes for this period were derived in two different ways for different time periods: 1915-28 and 1929-46. In the later period, indexes were taken from a supplement to the Survey of Current Business, "The National Income and Product Accounts of the U.S., 1929-1965, Statistical Tables,' pages 164-65. Indexes in this period are the same for both federal and state and local expenditures.

The indexes for the period from 1915 to 1929 are derived from the above indexes with 1929 as the base year. In R. W. Goldsmith, A Study of Saving in the United States, Vol. I, Table R-20, pages 608-609, ${ }^{10}$ there are several categories of indexes with base year $1929=100$. The categories are not as specific as our expenditure data call for, but since they are all that is available, we used the category which was the closest approximation to that needed. We took the 1929 figures from the OBE, and extrapolated backward, basing our work on Goldsmith's indexes in the following way, where the numbers in parentheses refer to columns in Goldsmith, A Study of Saving, Table R-20 and the weights are the price indexes for each category in 1929 with the base year equal to 1958. The formula we used is: $X_{1958}=$ Goldsmith index ${ }_{1929} \times$ index for 1929 $_{1958}$ :

Federal

| Residential | $(4) \times .592$ | Residential | $(4) \times .592$ |
| :--- | :--- | :--- | :--- |
| Nonresidential | $(3) \times .343$ | Nonresidential | $(3) \times .343$ |
| Highway | $(6) \times .475$ | Highway | $(6) \times .475$ |
| Conservation and develop- |  | Conservation and develop- |  |
| $\quad$ ment | $(3) \times .402$ | ment | $(3) \times .402$ |
| Military | (7) $\times .380$ | Sewer and water | $(8) \times .403$ |
| Other | (8) $\times .342$ | Public service | $(8) \times .403$ |
| Total | (8) $\times .413$ | Other | (8) $\times .342$ |
|  |  | Total | $(8) \times .413$ |

(4) $\times .592$

The price indexes for 1915 to 1946 are virtually the same for both federal and state and local.
(4) Estimates for 1893-1915. (a) Federal. Figures for these early years were taken from the Census Bureau publication, Historical Statistics of the United States-1789-1945, Table H: 27-32, page 169. The only available categories that correspond to the categories we used for later years were:

|  | Column |
| :--- | :---: |
| Total federal | 27 |
| Nonresidential | 30 |
| Conservation and development | 29 |
| Military | 28 |

[^5]The figures for the overlapping years (i.e., 1915 to 1919) show that the categories are not exactly the same but are close enough to be usable.

The price indexes for these early years were derived from the Goldsmith indexes in the same way as the later figures, described above.
(b) State and local. For state and local expenditures on structures, the only available data were for total expenditures. This "total" number was computed from Goldsmith's $A$ Study of Saving in the United States, Vol. I, as the sum of columns (2) and (6), Table G-6, page 1,053, and column (3), Table G-15, page 1,067.
(5) Federally Aided State and Local Construction Expenditures, 1915-66. From 1915 to 1956, the expenditure figures come from Construction Volume and Costs, 1915-1956, a statistical supplement to Construction Review, by the departments of Commerce and Labor.
For 1957-66, expenditure figures are not available by category. There is only a total federal aid figure for each year. We allocated this total among the components on the basis of the 1956 figures that were available from Construction Review (see above), using the following proportions: Public service enterprises, 0.014 ; highways, 0.860 ; nonresidential, 0.124 ; and sewer and water systems, 0.002 .

The same price indexes were used for the federal aid category as were used for state and local government expenditures.
d. Public Sector Equipment. Equipment stock figures were derived in the way described above for structures. The perpetual inventory method for computing net stocks and depreciation was applied to the investment series. Exponential or declining balance depreciation and a 12 -year average life are assumed for all categories.
(1) Federal Government. The federal equipment sector is broken down into "civilian" and "military." The military investment series for the early years from 1929 to 1946 come from R. W. Goldsmith, National Wealth of the United States in the Postwar Period, Table B-166, column (4), page 394. ${ }^{11}$ Data for the later years, 1947-68, come from unpublished data from the OBE. The early civilian series, from 1929 to 1946, comes from Goldsmith's A Study of Saving in the United States, Vol. I, Table F-16, column (8), page 1,009 . The sum of civilian and military invest. -ent figures gives the total of federal government equipment.
(2) State and Local Government. State and local expenditures for early years, from 1929 to 1946, come from A Study of Saving in the United States, Vol. I, Tables G-6, column (5), page 1,053, and G-15, column (3),

${ }^{\text {a }}$ Nonlinear depreciation over this life.
page 1,067. Expenditure estimates for 1947-68 are unpublished Commerce Department data.

The total of all equipment, federal and state and local, is available as a control total for equipment. This "total" figure can be found in OBE's publication, The National Income and Product Accounts of the United States, 1929-1965, and in the Survey of Current Business, July issues, Table 1.4, line 5.
e. Private Consumer Durables. The gross investment series in both current and constant prices are taken from the OBE's Tables 2.5 and 2.6, "Personal Consumption Expenditures by Type of Product," published regularly in the Survey of Current Business and in its supplements. Since the
flow of funds considers this to be capital expenditure rather than consumption, depreciation charges must be imputed to the household sector; stock estimates are a by-product of this calculation although they are not published.

The flow of funds estimates differ both in life assumption and in accounting convention from the earlier Goldsmith estimates. The flow of funds uses double declining balance depreciation, while Goldsmith used straight-line depreciation; he also assumed much longer lives than does the flow of funds. The comparisons are summarized in Table I-1. The flow of funds estimates were used (1) since they were readily available, (2) since they have been incorporated into the set of social accounts used elsewhere in the appendix, and (3) since the rates seem somewhat more typical of our present throw-away economy than do Goldsmith's. Estimates in preparation at OBE were not available, even in preliminary form, in time for inclusion here.
f. Inventories
(1) Private Nonfarm Inventories. Private nonfarm inventories are from the national income and product accounts. The levels are book values; the flows are the inventory change component of GNP and thus include the inventory valuation adjustment. The nonfinancial corporate and noncorporate business components are presumed to account for the total; no attempt was made to estimate inventory holdings for nonprofit institutions, households, and financial corporations.
(2) Farm Inventories. Like the estimates of nonfarm private inventory investment, the change in farm inventories was also obtained from the OBE. Year-end holdings come from the Balance Sheet of Agriculture, various issues; this series is the sum of "livestock" and "crops stored on and off farms" less "CCC loans" and "CCC-backed loans" from the flow of funds accounts.
(3) Federal Government Inventories. Federal inventory year-end levels are taken, for recent years, from Treasury Department data. The Treasury Bulletin contains a quarterly balance sheet for "corporations and certain other business-type activities." The table ending December 31, which usually appears at the end of the April Bulletin, was used for each year. From 1956 to 1968, we took the total inventories for all corporations and subtracted from them inventories of the Defense Department, assets of the Panama Canal Corporation being considered civilian. We then added to this figure Commodity Credit Corporation gross "loans receivableU.S. dollar loans" and the flow of funds figure for CCC-backed loans. This procedure gives total federal inventory levels for each year.

From 1952 to 1955, this computation is made difficult by the fact that the Treasury Department had a different balance sheet and different categories during these years. Prior to 1956, defense assets are not included in the table, and the "total inventory" figure is far lower than the comparable total in the later years. Even with defense inventories eliminated from the total in 1956, the 1955 "total". is half of the 1956 "total." The difference is attributable in part to the fact that General Service Administration and Defense Department inventories are left out in the early years. Since we did not want to include defense inventories, the addition of GSA inventories was all that remained. The largest component of GSA inventories was the category "strategic stockpiles." Goldsmith's estimates of "strategic stockpiles" ${ }^{12}$ seem to correspond with GSA "strategic stockpiles" from the Treasury Bulletin for the years after 1955, and were therefore deemed adequate. To the sum of "total inventories" and GSA "strategic stockpiles," we then added both sets of CCC loans to give the total federal inventory figure for 1951-55.

Annual flows are measured by changes in this stock so defined.
(4) State and Local Government Inventories. No estimates were made of the inventories of state and local governments. Goldsmith's earlier work was based on fragmentary evidence which is now out of date.

## C. NEW SECTORS

## 1. Investment Companies

Although the flow of funds accounts include those open-end investment companies which are members of the Investment Company Institute, other investment companies are treated only implicitly, if at all. Their retained earnings are included in the gross saving of the flow of funds investment company sector, since the national income and product accounts do not make a distinction between open-end and closed-end companies.

The estimates presented in this study distinguish between open-end companies and all other registered investment companies. The general procedure employed was first to develop balance sheets for the various types of companies, using the SEC series on total assets as the basis for universe asset holdings, and then to distribute this total among the various asset categories on the basis of sample data. With the exception of common stock, flows were taken to be the difference in balance sheet values of the

[^7]various assets. For stock, in cases where direct flow estimates were not available, an attempt was made to separate unrealized capital gains from net purchases by means of the Standard and Poor's 500 -stock price index. The flows thus derived were used as a first approximation; some of them were later modified to reconcile aggregate information from SEC and national income accounts.
a. Open-End Companies. The Investment Company Institute data form the basis of this sector. In the flow of funds accounts, these ICI members are the only companies included. However, data from the SEC on June 30 assets of active registered open-end companies are somewhat larger than the ICI total. Goldsmith's estimates for those years for which the SEC series is not available indicate the same state of affairs. ${ }^{13}$ Therefore estimates for non-ICI open-end companies were made as follows. For years in which the SEC totals were available, the June 30 ICI asset, were subtracted and the non-ICI residual was moved to a December 31 basis, using the assumption that the June-to-June increase in assets for non-ICI members took place over time in the same pattern as did that of ICI members. For earlier years, Goldsmith's estimates of the end of year total were used to derive the non-ICI total. It was further assumed that these non-ICI mutual funds had the same portfolio composition as did the ICI members, and that their net purchases of stock bore the same relationship to the change in their holdings of stock as did the purchases of ICI members. ${ }^{14}$
The balance sheet for all open-end companies appears in Table IA-8; their stock purchases are given in Table IA-22.
b. Other Investment Companies. Separate estimates were made for closedend companies, face-amount companies, and unit trusts.

Estimates of total assets for closed-end companies were derived by linking the Goldsmith series ${ }^{15}$ on total assets to the SEC total asset series whose June 30 observations had been put on an end-of-year basis by interpolation. From this total were subtracted the assets of Christiana Securities and, for the two years in which they existed, the assets of dualpurpose funds. ${ }^{16}$ This residual estimate of the assets of closed-end companies other than Christiana and of the dual-purpose funds was distributed among the various classes of assets on the basis of portfolio composition

[^8]data obtained from a sample of 30 companies; ${ }^{17}$ to these estimates were added the assets of Christiana and of the dual-purpose funds. With the exception of stock, net purchases of all assets were taken to be equal to the observed change in the balance sheet over the period; in the case of stock, this change was adjusted to allow for appreciation as measured by the Standard and Poor's 500 -stock price index. Stock transactions for Christiana were taken directly from company statistics.
Face-amount companies are dominated by Investors Diversified Services (IDS) and Investors Syndicate of America (ISA). Therefore, the estimates for this group consist of Moody's reports on these two companies blown up slightly to allow for the remaining 5 percent of the assets held by other companies. The flows were derived in the way described above.

In order to estimate the assets of unit trusts, a total asset figure was derived from the SEC June 30 observations. Since the SEC Annual Report contains estimates of the fraction of these assets which represent shares in other investment companies, these assets were consolidated out of this sector. The remaining assets were assumed to be either tax-exempt bonds or common stock; a brief survey of the various unit trusts represented in Moody's Bank and Finance Manual indicates that these companies exist for the accumulation of mutual fund shares, for the accumulation of specific stock, and for the purchase of tax-exempt securities. Estimates of the net issues of, and security purchases by, tax-exempt bond funds were obtained from the SEC; assets which were neither municipals nor investment company shares were assumed to represent common stock. Net purchases of the latter were estimated as described above for closed-end companies.

Liabilities and share values and issues were estimated in several ways. Open-end companies have only short-term liabilities, and in the ICI data these are netted against cash; the value of mutual fund shares is thus equal to the net asset value of the fund. Closed-end company shares typically trade at a discount (or premium) relative to net asset value. Unit trusts distribute portions of the trust corpus as well as paying out the earnings; the redemption value of units can also vary with the market value of the securities. Prices of shares in IDS and ISA also seem to be less than assets per share. This suggests that in deriving an estimate of the market value of the shares of investment companies other than mutual funds, some write-down of their assets should be made.

[^9]The debt of non-open-end companies was taken from Moody's reports on IDS, ISA, and "Closed End Companies with Senior Capital." Total share issues are the SEC's series on net issues of investment company shares; the breakdown by type of company was supplied by the SEC.

The balance sheet for the aggregate of these three investment company sectors is given in Table IA-9; stock purchases for this aggregation appear in Table IA-22.

## 2. Bank-Administered Personal Trusts and Estates

a. Introduction. The estimates discussed here refer to the amount and composition of the assets held in personal trusts or in estates under bank management. Banks manage other types of accounts, and in fact, these other accounts constitute the more important portion of their business. Data exist on the activities of trust departments as a whole, however, for only a small portion of the period under discussion. The assets of those employee benefit accounts which are bank-managed are presumably covered in the statistics on noninsured pension funds, and the bank has somewhat less freedom in decision-making for agency than for trust accounts. ${ }^{18}$

For the period for which data on activities of the entire department exists, some rough estimates were made of the holdings of employee benefit trusts and of agency accounts. These estimates were used as checks on the reasonableness of the estimates of personal trusts and estates. No attempt was made to derive a time series covering the entire portfolio under bank management:

In section b which follows we discuss the sources of information available at the time the estimates were made. Section c contains a description of the estimating procedure used in the two periods into which the nature of the source material available divides the estimates. In this section data are presented on common trust funds, the only component of personal trusts and estates for which a continuous time series is available for a long period of time.
b. The Nature of the Data. With the exception of the early Federal Reserve surveys of common trust funds, the only observations available are of holdings at a point in time; there are no turnover data other than those for common trust funds from 1954 through 1962. Even the balance

[^10]sheet data which do exist cannot be put together in a satisfactory way to construct a time series; for they cover a different set of institutions, they cover a different set of accounts within these institutions, and the date of the observations varies from year to year. The available material is as follows:

1. American Bankers Association's Surveys of Personal Trusts. ${ }^{19}$ These contain the value of assets on June 30, for the years 1958, 1959, 1960, and 1963. They cover only personal trusts, whereas estates are commingled with the personal trusts in subsequent bodies of data. Furthermore, the sample used in these surveys has been questioned by some researchers.
2. Comptroller of the Currency's Reports of the Trust Assets of National Banks. These surveys, which include all types of accounts, cover the period 1963 through 1968, although portfolio detail by type of account is available for only the last three years of the period. Some estimates of the assets managed by state-chartered banks were made, but they are highly aggregative and impressionistic. These estimates apply to the end of calendar years; some effort was made to adjust the data for valuation date discrepancies. ${ }^{20}$
3. The Patman Report, "Commercial Banks and their Trust Departments." This report provides, for the first time, estimates of the assets managed by the entire trust department for all banks as of the end of 1967. The questionnaire, however, contained too little detail by asset group, by account category, and by a cross classification in these two dimensions to be useful for anything more than a broad check on the estimates derived by other means. ${ }^{21}$

[^11]4. Trust Assets of Insured Commercial Banks. This survey, conducted by the three bank regulatory agencies, gives universe estimates for all banks as of the end of 1968, cross-classified by asset and by type of account. The portfolio breakdown, while not very detailed, is much less aggregated than that provided by the Patman report. ${ }^{22}$
5. The Goldsmith estimates reported in Volume II of Studies in the National Balance Sheet, consist of a merger of the ABA surveys available at the time and the earlier estimates of R. W. Goldsmith and Eli Shapiro, "An Estimate of Bank Administered Personal Trust Funds," Journal of Finance, March 1959. These figures again may be presumed to cover only personal trusts, with no allowance for estates, agency accounts, or employee benefit accounts.
6. Common Trust Funds have been surveyed both by the Federal Reserve and by the Comptroller of the Currency. Although they account for only a small portion of the assets held in personal trusts and estates, time series of balance sheets and of transactions data for these funds from 1954 to 1968 do exist. Some performance data are also available. ${ }^{23}$
7. Fiduciary Income Tax Returns. These triennially tabulated returns give some information on property income by type, on expenses, and the like. There is also information on the fraction of fiduciary income accounted for by estates as opposed to trust accounts, and for 1962 it is possible to ascertain the fraction of fiduciary income accruing on the property managed by banks.
c. Estimating Procedure: Balance Sheets. From the discussion thus far, it is clear that we have two periods with entirely different data sets and capabilities. From 1963 on we have a fair amount of information about the assets managed by national banks; we even have some ideas about the variations in portfolio composition as a function of account type. Given the universe estimates for 1968 and to a limited extent for 1967, it is possible to derive estimates of the portfolios of all bank trust departments by type of account for these years.

Since the longest real time series of annual observations is the series on national banks which has resulted from the surveys of the Comptroller of the Currency, the procedure adopted was first to. fill in the missing

[^12]cells on asset types by type of account for the years 1963-65. These figures were then expanded to a total for all banks on the basis of the relationships between state and national banks from the 1968 survey, the Patman study, and some of Silverberg's early estimates.
(1) National Banks, 1963-68. Available data from 1966 to 1968 frequently take the form of portfolio percentages; late and incomplete responses frequently led to the reporting of total assets in dollars and a percentage distribution of the portfolio which was observed. Since these portfolio coefficients are somewhat easier to interpret than are dollar amounts of assets, these coefficients were estimated directly. The only time series of portfolio coefficients for the entire period is that for all trust accounts, covering both personal and employee benefit accounts. The total value of assets for all types of accounts is also known for the entire period. The task is then to estimate a set of account coefficients such that when they are summed over all types of accounts, the results will not conflict with the portfolio composition given for the entire department.

One might first assume that these coefficients are the same for all accounts and thus use the department portfolio as the model for both personal trusts and estates and for employee benefit accounts. The evidence available for 1966-68, however, indicates that this assumption is not likely to be true. One might also assume that the coefficients for a particular type of account are constant or move in some simple or regular way over time. Again evidence suggests that this is not a very reliable assumption, and these ratios seem far from predictable on the basis of the brief bit of history we have at our disposal. Finally, we can look for some consistency in an accounts' share in the department's holding of a particular asset. These ratios did in fact prove stable, and this extrapolation was used to produce initial estimates of these account-specific coefficients.

This method in effect assumes that overall investment policy is set for the department, and that the managers of specific classes of accounts attempt to maintain some relative share of total departmental holdings of the asset in question. Any further adjustments in these portfolio coefficients were made in order to meet the accounting constraints in ways which were most consistent with external evidence and with notions of reasonable portfolio policy dictated by the subsequent development of the accounts involved. In particular, employee benefit trusts were adjusted on the basis of some relationships observed between employee benefit trusts and existing data on private noninsured pension funds, which are largely managed by banks. These considerations constrained the estimates
for personal trusts and estates sufficiently to permit making the final estimates for national bank portfolio coefficients shown in Table IÁ-10.
(2) All Bank Estimates, 1963-68. Currently (1970), the only detailed portfolio estimates by type of account are for 1968. The Patman data for 1967 are too aggregated to be of much use in the particular task of estimating the portfolio composition of personal trusts and estates. The early Silverberg estimates relied a bit too heavily on inferences from the portfolios of private noninsured pension funds. For those years, data on portfolio composition by account type are not available even for national banks. We have decided, by default, to accept the time series from these sources on the total assets under management by type of account for all insured banks; but, with the exception of 1968, the earlier estimates of the portfolio composition of these totals were used as checks on our results rather than taken as given. Final estimates were obtained by stepping up the national bank portfolio coefficients by factors derived as the 1968 ratios of all bank to national-bank coefficients. These factors were weighted so as to allow for differences over time in the relative shares of personal trusts and estates in total trust assets for the two sets of banks. The coefficients which result are shown in Table IA-11.
(3) Estimates Before 1963. Before 1963 nothing is known explicitly about the employee benefit accounts managed by banks. Existing personal trust estimates refer only to that category of account; thus, the series before and after 1963 are not really comparable, since it is impossible to separate out estates completely from the latter numbers. There is also the problem of converting June 30 data to a year-end basis. Evidence in recent years suggests that most accounts are reviewed during the last quarter of the year; therefore, giving the option of reporting assets at market value as of the last review date before June 30 would tend to produce estimates of the market value of holdings as of the end of the preceding year.

The ABA data also show "units of participation in common trust funds" as a separate asset category, while the questionnaires of the later period ask that the assets held by the common trust fund be distributed among the appropriate categories. Since the valuation date for the common trust fund is somewhat more likely to have occurred on June 30 than is the valuation date for the other accounts in the personal trust category, we first netted out common trust funds from the ABA reports. Subsequently, the time series of end-of-year observations on common trust funds covering the bulk of this early period is added to the end-of-year estimates of the other personal trust accounts.

The estimates for the period before 1963 were based in large measure
on the previous work of Goldsmith. His series on personal trusts other than common trust funds was used through 1957; his procedures were then used in interpolating between the ABA surveys, most of which were not available to Goldsmith at the time his estimates were prepared. In this procedure, one assumes that the ABA's reported values of assets other than corporate stock are an adequate measure of the value of these assets on December 31 of the previous year. Holdings of corporate stock were estimated by assuming that net purchases occurred at a uniform rate over the period in question, and that the pattern of the change in holdings not so accounted for followed the time path of the Standard and Poor's 500 -stock price index.

Efforts to apply this method of allowing for price movements in other assets proved less successful; the results for common trust funds did not recapitulate known net acquisitions for these funds. The difficulties of using the existing bond price indexes; the lack of detail on the characteristics of the bond portfolios of these funds, which made it difficult to select among the price indexes and the poor results with the common trust funds, made it seem unwise to attempt to account for any but the most obvious effects of security price movements, i.e. those involved with common stock. The results of these manipulations are shown in Table IA12, panel A.

In order to make this series comparable with the estimates for later years, three further steps were necessary. First, the series had to be adjusted upward to include estates as well as trusts; this was accomplished by stepping up trust assets by a factor derived from IRS statistics of fiduciary income. This factor is the reciprocal of the share of income from trusts in total income paid by fiduciaries, adjusted for differences in bank fiduciaries' shares of the income from trusts and from estates. Allowance was made for differences in portfolio composition between trusts and trusts and estates on the basis of the relationships prevailing in 1968, the year for which such data by type of account existed. The results of this process are shown in Table IA-12, panel B.

The second step involved adding in the series on common trust funds taken from the Federal Reserve Board's surveys for all but the first two years; these are from Goldsmith's estimates. This series and the results of the addition are shown in Table IA-12, panels C and D. Finally, the large "other assets" category was allocated among time deposits, real estate, and miscellaneous on the basis of the average contribution of these three components to this sum in the years for which the breakdown was available.

The final time series, covering the entire period 1951-68, is given in Table IA-14. The flows were taken to be equal to the first differences in this balance sheet for all assets except corporate stock. The problems of measuring net purchases of stock will be discussed for all the new sectors together in a later section of this appendix.

## 3. Selected Nonprofit Institutions

This sector is constructed out of several independent elements. The estimates of income, fixed investment, and consumption expenditures of nonprofit institutions are those appearing in the OBE's national income and product accounts. Appendix III's estimates of the income, outlay, and balance sheets of foundations, colleges, and universities provided estimates of the financial assets of these institutions; these were supplemented by the estimates of the financial assets of labor unions in Appendix IV in order to yield the estimates of financial assets for the entire sector. Flow of funds accounts estimates of the debt of nonprofit institutions were used on the liabilities side. Finally, the estimate in Appendix II was used for institutional land.

Thus, the estimates grouped under the label "selected nonprofit institutions" do not provide a reliable picture of the role of nonprofit institutions in the economy, nor of the size of their assets. Presumably, the estimates of tangible assets, of income, and of consumption cover all nonprofit institutions. The estimates of financial assets cover only three institutional groups, however; religious organizations and hospitals are obviously major exclusions. To assume that this collection of estimates constitutes a valid approximation of the nonprofit sector is to assert that the holdings of the excluded institutions would make relatively little contribution to the total financial assets of all nonprofit institutions.
It is therefore preferable to consider the aggregates listed under "selected nonprofit institutions" as an attempt to collect known elements of assets, liabilities, and transactions which do pertain to nonprofit institutions, and which belong neither to households proper nor to any other sector in the present scheme of things.
The financial assets in the balance sheet were taken from the work of Nelson and of Troy as reported in Appendixes III and IV of this report. In the case of foundations, estimates began only in 1953; for colleges and universities, estimates were available only for 1953-66. Since the transactions estimates were based on first differences in the balance sheets, a time series covering the years 1951-68 was necessary; and we extrapolated

Nelson's estimates after consultation with him on the appropriate methodology. Troy's time series on total assets and total liabilities were used, the portfolio composition was taken to be the same as that reported for the more limited aggregates, and the 1962 breakdown was used for earlier years.

We have already pointed out that the estimates of the transactions in financial assets were derived from the change in balance sheet holdings. This is true for all assets with the exception of corporate stock; here an adjustment was made to allow for price movements, details of which are given below in section D2. No such adjustment was made for the assets of labor unions, since the reported holdings are valued at cost rather than at market.

## 4. Assets of Fraternal Life Insurance Companies, 1951-68

The assets of fraternal life insurance companies in Table IA-15 are derived from accompanying Tables IA-16 and IA-17. Table IA-17 shows the percentages allocated to each asset in a given year by the ten largest fraternal life insurance companies. ${ }^{24}$ Total assets for all fraternal life insurance companies, shown in column 2 of Table IA-16, come from the Life Insurance Fact Book. Table IA-16 also shows the percentage which the assets of the ten largest companies comprise of total assets of all companies (column 3). In Table IA-15, the percentages from Table IA-17 are applied to the total assets of all fraternal insurance companies (Table IA-16, column 2) to arrive at the comprehensive breakdown of assets for all companies for the entire period.

The sector accounts for fraternal insurance presented in Appendix I are based on these data. The composition of the bond account was estimated for 1951 and 1952 in order to derive both flows and balance sheets for 1952. Throughout the period covered, the "unallocated bonds" were assumed to be an addition to "corporate and foreign bonds" held by the sector. Other assets were placed in the "unallocated" category. By analogy with the flow of funds treatment of private insurance and pension funds, their liabilitity for policy reserves was taken to be equal to the value of their assets.

With the exception of corporate stock, the flows are taken to be equal to the change in the holdings as shown on the balance sheet. For stocks, an attempt was made to allow for the appreciation shown by the DowJones Industrial Index in defining net purchases.

[^13]
## 5. Mortgage Bankers

These institutions are included in the finance company sector of the flow of funds accounts; thus nothing else in the system is changed by their inclusion or exclusion from explicit consideration. Such stockholdings as they may have are negligible. The data which are given in Table IA-18, therefore, appear here only for the sake of completeness.

From 1951 to 1954, the estimates are those appearing in Saul B. Klaman, The Postwar Rise of Mortgage Companies, New York, NBER, 1959. The estimates for 1955 to 1968 are those of the Mortgage Bankers Association; they appear in various issues of Mortgage Banking.

## D. CORPORATE SECURITIES

## 1. Value of Corporate Bonds Outstanding

The present flow of funds series consists of Hickman's estimate of the par value of corporate bonds outstanding ${ }^{25}$ increased each year by the SEC's estimates of net change in corporate debt securities outstanding. ${ }^{28}$ Meiselman and Shapiro derived similar series for several industrial groups of corporations, as well as for the aggregate of nonfinancial corporations. ${ }^{27}$ The latter differs from the flow of funds series by amounts which vary from year to year. Since the Meiselman and Shapiro series ends in 1958 and its divergence from the present flow of funds series seems to be the result of statistical revisions for the most part, the flow of funds estimates must be used by default.

Unfortunately, the inclusion of the new institutional sectors for purposes of this study adds reported institutional bond holdings for some years in excess of the residually estimated flow of funds "household" bond holdings. Clearly the bond holdings of these new sectors may be overstated. It is also the case, however, that the SEC net change series has not been checked against a benchmark, since none has been available; and questions have been raised about the completeness of the net change series for many years.
We therefore attempted to provide such a benchmark for 1966 and then to adjust the annual flows in such a way as to account for the change

[^14]in the par value of corporate bonds between the Hickman study and 1966. The new series is given in Table IA-19.
The resulting series is a par value series, as is the flow of funds series which it replaces. It consists of the published series on the outstanding debt of railroads and utilities, the flow of funds estimates of the outstanding debt of financial institutions, and an estimate of industrial bonds and notes consistent with the totals derived from summing individual company data for all relevant companies in Moody's 1967 Industrial Manual. Each of these components is described below.
a. Regulated Industries. Data on long-term debt oustanding were taken from statistical reports of regulatory agencies and trade associations.

1. Railroads: Data are those of the Interstate Commerce Commission, Statistics of Class I railroads, as reported in Moody's Transportation Manual 1969, pages a49 and a50. The sum of "funded debt unmatured," "equipment obligations," and "long-term debt in default" was adjusted upward to allow for switching and terminal companies and other differences between Hickman's estimates and the ICC series.
2. Electric Utilities: Data were taken from the Federal Power Commission's Statistics of Privately Owned Electric Utilities in the United States, various years. The series used was "bonds less bonds reacquired" for class A and B electric utilities.
3. Gas Utilities: Data were found in the American Gas Association's Historical Statistics of the Gas Industry, 1963, and Gas Facts, various issues. The series used covers bonds and debentures of all investor-owned firms in the gas utility and pipeline industries.
4. Telephone and Telegraph: Data were obtained from the Federal Communications Commission's Statistics of Communications Common Carriers, various years. Telephone bonds consist of "mortgage bonds," "debentures," and "other funded debt" of annually reporting Bell companies, annually reporting non-Bell companies, and "selected large telephone carriers not subject to the reporting requirements of the commission." Telegraph bonds cover funded debt of both domestic and overseas carriers.
b. Industrial Bonds and Notes. A 1966 benchmark was obtained by summing the long-term debt exclusive of mortgages (bonds and notes including private placements) for all domestic corporations listed in the 1967 edition of Moody's Industrial Manual, with some adjustment for the fact that end-of-year data were not available for certain companies. In addition, a similar estimate was derived for nonrail transport, since such companies have issued bonds and their debt was reportedly included in Hickman's
benchmark for utilities in 1943. From this total was subtracted Hickman's estimate for "industrial bonds" for 1947, augmented by the difference between Hickman's "utility" estimate and the sum of the utilities estimates described above. The SEC series on net change in industrial and nonrail transport debt outstanding was then stepped up by a factor defined as the ratio of the benchmark difference to the sum of cumulated net change from 1948 through 1966; and a series on outstandings was derived by the same method employed in the flow of funds estimate, using this revised investment series. No revision was made in the net change series for 1967 and 1968.
c. Finance. This series is taken directly from the flow of funds. It consists of the bonds of banks and finance companies.

## 2. Corporate Stock

The value of outstanding domestic stock other than investment company shares shown in Table IA-20 is the series given in Appendix VI of this report with minor modifications occasioned by the substitution of a more refined estimate of investment company shares elsewhere in the system. The estimates of foreign stock held by U.S. residents come from the balance of payments statistics and are incorporated into the flow of funds accounts.

The domestic total was allocated between the stock of nonfinancial corporations and of all financial corporations on the basis of the data on the industrial composition of outstanding stock appearing in Appendix VI. The estimate of financial stock outstanding was interpolated and extrapolated by the finance component of the NYSE stock price index. Net issues are the sum of investment company net issues and the bank issues from the flow of funds. The estimates for nonfinancial corporations were then derived residually.

The net issue series all come from the SEC series "net change in corporate stock outstanding," and these are shown in Table IA-22. The net purchases were taken from the flow of funds accounts, with the exception of households, nonprofit institutions, and the newly created financial institutions.

For all but households, the estimates of Table IA- 22 were derived from the holdings data of Table IA-21 and the indicated price index, using the relationship

$$
A_{t}=\left(A_{t-1} \frac{P_{A}}{P_{t-1}}+\mathcal{N}_{t}\right) \frac{P_{t}}{P_{A}}
$$

where:
$A_{t}=$ holdings at the end of year $t$
$P_{t}=$ price index at the end of year $t$
$P_{A}=$ midyear price during year $t$, and
$N_{t}=$ net purchases during year $t$.
The resulting series are quite noisy; however, the attempt to use a confidential SEC series on net purchases by all investment companies produced an even more peculiar series for nonmutual funds when the open-end purchases were netted out.

TABLE IA-1
Replacement Cost of Consumer Durables and Estimates of Land Values Not Appearing in Appendix II
(\$million)

## E. SECTOR BALANCE SHEETS

These balance sheets are the result of supplementing the flow of funds accounts with the data discussed in sections B through D of this appendix. The aggregate corporate stock and bond series were replaced by those covered in section D. The estimates of tangibles from section B were added to these modified flow of funds estimates of financial assets and liabilities in order to produce the full balance sheets of Tables IB-1 through IB-9.

The remaining differences between these estimates and the flow of funds accounts come from two sources. One is the difference in sectoring which results from the exclusion of some nonhouseholds from the household sector given here. The other is the differences in asset categories which result from a higher degree of aggregation.

The entries for the NBER finance sector exceed the corresponding flow of funds aggregates by an amount equal to the sum of the holdings of personal trusts and estates, fraternal insurance companies, and those investment companies not members of the Investment Company Institute. The holdings of the NBER's household sector are less than the corresponding household holdings in the flow of funds accounts by the amount of the holdings of these newly created financial institutions; in addition, the portfolios of nonprofit institutions have been subtracted from the flow of funds household account as well. Additional assets in the form of claims on life insurance and personal trusts were given to the remaining household sector by analogy with the treatment of life insurance and pension fund claims in the flow of funds accounts. Finally, since household holdings of corporate bonds and stock are derived residually, the holdings reported in Table IB-2 also reflect the difference between the series on corporate securities outstanding in the two systems.

The asset categories differ from the flow of funds categories in several additional respects. "Monetary reserves" is the sum of the flow of funds categories gold, foreign exchange, and Treasury currency. Currency and demand deposits, time deposits, and short-term U.S. government securities are equivalent in the two systems. "Other short-term claims" consists of bank loans n.e.c., other loans, consumer credit, security credit, trade credit, taxes payable, and interbank items.

The bonds entry in the present accounts covers all U.S. government and agency issues not included in the short-term claims, state and local government securities, and corporate and foreign bonds, the latter modified as described above. Mortgages covers all mortgages in the flow of
funds system; claims on life insurance, pension and personal trusts consists of the flow of funds items life insurance reserves and pension fund reserves plus the total assets of fraternal insurance and of bank-administered personal trusts.

The estimate of corporate shares is the total discussed above in section D2. Equity in unincorporated business is equal to the sum of the net worth of farm and nonfarm noncorporate business. Miscellaneous assets and liabilities are taken directly from the flow of funds accounts; thus the category includes direct investment, other identifiable claims, and various floats and unallocated items.

The totals shown here are those for all domestic sectors. In addition to the discrepancy for any instrument between total assets and total liabilities introduced by removing the rest of the world sector from the flow of funds accounts, there are other discrepancies in the system as well. Bank and holder records differ on currency and demand deposits; the trade credit and miscellaneous accounts both show discrepancies in the flow of funds. These have been preserved in the balance sheet tables appearing below.

TABLE IB-9
Balance Sheet, Financial Institutions, 1952, 1960, and 1968
(\$billion)

|  | 1952 | 1960 | 1968 |
| :--- | ---: | ---: | ---: |
| Tangible assets | 5.1 | 13.2 | 28.5 |
| Land | 0.6 | 2.3 | 7.2 |
| Reproducible tangible assets | 4.5 | 10.9 | 21.3 |
| Structures | 2.5 | 5.6 | 12.3 |
| Producer durables | 2.0 | 5.3 | 9.0 |
| $\quad$ Inventories | - | - | - |
| Financial assets | 441.7 | 741.3 | $1,432.3$ |
| Monetary reserves | 27.9 | 22.9 | 19.2 |
| Currency and demand deposits | 7.9 | 11.2 | 17.0 |
| Short-term claims | 135.4 | 206.9 | 405.6 |
| Time deposits | 1.2 | 1.3 | 3.2 |
| Short-term U.S. government securities | 43.7 | 50.8 | 76.5 |
| Other short-term claims | 90.5 | 154.8 | 325.9 |
| Long-term claims | 227.6 | 382.9 | 702.4 |
| Bonds | 156.9 | 212.9 | 350.7 |
| Mortgages | 70.7 | 169.9 | 351.8 |
| Claims on life insurance, pensions, and |  |  |  |
| $\quad$ personal trusts | - | - | - |
| Corporate shares | 37.0 | 102.6 | 253.0 |
| Equity in unincorporated business | - | - | - |
| Miscellaneous assets | 6.0 | 14.6 | 35.2 |
| Total assets | 446.8 | 754.5 | $1,460.8$ |
| Total liabilities | 404.8 | 666.1 | $1,282.2$ |
| Monetary reserves | - | - | - |
| Currency and demand deposits | 137.4 | 152.2 | 211.1 |
| Short-term debt | 118.7 | 218.5 | 491.8 |
| Time deposits | 84.9 | 176.8 | 412.1 |
| Short-term U.S. government securities | - | - | - |
| Other short-term debt | 33.8 | 41.7 | 79.7 |
| Long-term debt | 125.5 | 249.4 | 479.8 |
| Bonds | 4.4 | 17.8 | 42.6 |
| Mortgages | 0.5 | 1.2 | 2.4 |
| Claims on life insurance, pensions, and | 23.2 | 46.0 | 43.8 |
| personal trusts | 42.0 | 88.4 | 178.6 |
| Miscellaneous liabilities |  |  |  |
| Net worth |  |  |  |

[^0]:    ${ }^{1}$ Board of Governors of the Federal Reserve System, Flow of Funds Accounts 1945-1968, Washington, D.C., 1970.

[^1]:    ${ }^{2}$ The value of investment company shares outstanding differs from the estimates of Appendix VI. See sections Cl and D 2 below.
    ${ }^{3}$ At the time of writing, publication of full balance sheets for major sectors on a flow of funds basis was planned.

[^2]:    ${ }^{4}$ For a recent publication describing the OBE estimates see Robert C. Wasson, John C. Musgrave, and Claudia Harkins, "Alternative Estimates of Fixed Business Capital in the United States,' Survey of Current Business, April 1970, pp. 18-36.
    ${ }^{5}$ The allocation between corporate and noncorporate is based on the study reported by Allan Young in "Alternative Estimates of Corporate Depreciation and Profits: Parts I and II,' Survey of Current Business, April 1968, pp. 17-28, and May 1968, pp. 16-28.

[^3]:    ${ }^{6}$ See Wasson, Musgrave, and Harkins, op. cit., for a discussion of these valuation methods.

[^4]:    ${ }^{7}$ H. S. Tice, "Depreciation, Obsolescence and the Measurement of the Aggregate Capital Stock of the United States," Review of Income and Wealth, June 1967, pp. 119-54.
    ${ }^{8}$ The application of this test is made more complicated by the fact that the Census estimates measure the value of "real estate," and there exists little evidence on how these estimates should be divided between land and structures. Unfortunately we have no independent estimates of the value of residential land. In Appendix II the land underlying multifamily dwellings is included in the IRS-based estimates of the land holdings of business firms; the value of the land underlying $1-4$ family structures was derived as a fraction of the value of those structures. The OBE has completed estimates of the housing stock since this report was written. See Allan H. Young, John C. Musgrave, and Claudia Harkins, "Residential Capital in the United States, 1925-70,' Survey of Current Business, November 1971, pp. 16-27.

[^8]:    ${ }^{13}$ Goldsmith and Lipsey, op. cit., Vol. II, pp. 168-69.
    ${ }^{14}$ In the case of portfolio composition and change, the flow of funds breakdowns of the ICI data were used.
    ${ }^{15}$ Goldsmith and Lipsey, op. cit., pp. 170-71.
    ${ }^{18}$ These companies were first formed in 1967.

[^9]:    ${ }^{17}$ The data for the sample and for dual-purpose funds were taken from Moody's Bank and Finance Manual and from Arthur Weisenberger Co., Investment Companies, various issues. Information about Christiana came from Moody's.

[^10]:    ${ }^{18}$ On the basis of the IRS tabulations of the 1962 fiduciary income tax returns, banks account for only about one-half of the personal trust and estate business. See Internal Revenue Service, Statistics of Income-1962, Fiduciary, Gift, and Estate Tax Returns, Washington, D.C., 1965; and ibid., 1965, Washington, D.C., 1967.

[^11]:    ${ }^{19}$ American Bankers Association, Trust Division, "National Survey of Personal Trust Accounts,' New York, 1959, 1960, 1961, 1965, mimeographed.
    ${ }^{20}$ The results of these surveys were published in a series of articles in the National Banking Review and in a recent paper by Hanczaryk. For further information the reader should consult Stanley Silverberg, "Bank Trust Investments: Their Size and Significance," National Banking Review, June 1964; "Growth and Performance of Common Trust Funds in 1964,'' ibid., June 1965; ''Bank Trust Investments in 1964,'’ ibid., June 1965; and 'Bank Trust Investments in 1965,'" ibid., June 1966. There are some additional papers by Edwin W. Hanczaryk: 'Growth and Performance of Common Trust Funds in 1966," ibid., June 1967; and Bank Trusts: Investments and Performance, Department of Banking and Economic Research, Office of the Comptroller of the Currency, Washington, D.C., 1970, mimeographed. Mr. Hanczaryk was kind enough to provide us with a copy, of the last of these manuscripts before its publication.
    ${ }^{21}$ U.S. Congress, House Committee on Banking and Currency, Commercial Banks and Their Trust Activities: Emerging Infuence on the American Economy, 90th Cong., 2nd sess., Washington, D.C., July 1968.

[^12]:    ${ }^{22}$ Board of Governors of the Federal Reserve System, Federal Deposit Insurance Corporation, and Office of the Comptroller of the Currency, Trust Assets of Insured Commercial Banks-1968, Washington, D.C., October 1969. This survey has been continued on an annual basis.
    ${ }^{23}$ The estimates appear in the Silverberg and Hanczaryk articles cited previously for 1963-68. Estimates for earlier years are found in articles with the general title, "Survey of Common Trust Funds,' which appeared in the Federal Reserve Bulletin of June 1957, May 1958, May 1959, May 1960, May 1961, May 1962, and June 1963.

[^13]:    ${ }^{24}$ The figures for these ten largest companies come from survey reports and from Best's Life Insurance Report.
