Chapter pages in book: (p. 341-362)

## Other Than Steam Railroad Transportation

So far we have confined our discussion of cycles in transportation to the railroad industry. For years long past, and for most aspects of the subject even in recent times, this was not a matter of choice. Continuous records such as we need have not, with a few exceptions, been kept for domestic waterborne commerce, pipe lines, or highway traffic. Aviation is a newcomer; commercial planes operated on only a minute scale at the beginning of the last business cycle to close before this inquiry was undertaken. What figures we do have for transport other than by steam railroads pertain mainly to the movement of traffic; data on employment, fuel consumption, movement and stocks of equipment, revenues, costs, and profits are scarce indeed. What we have to report about the other means of movement can be told in one chapter.

TRANSIT

## Nature of the industry

Perhaps the most familiar of the other commercial kinds of transport is the transit industry, whose facilities city people use in traveling to and from work, shopping, going to the big downtown movie houses, making short visits to relatives and friends, and to some extent in the course of transacting business, such as collecting bills and delivering packages.

Before 1920 travel of this kind, after the early horse-car era, was provided for almost entirely by electrically operated cars running on tracks. But since then a progressively increasing portion has been accommodated in busses. The economic purposes the two means of transport serve are very similar. Often one company operates both kinds of vehicle, or operates trolley cars while a subsidiary operates busses. Bus companies and electric traction companies should be regarded for our purpose as comprising a single industry; the number of bus rides should be added to the number of car rides to measure its total performance.

The routes of many companies that operate transit facilities within cities extend beyond municipal limits. Some of these opera-
tions serve only to connect a city with its suburbs. Others connect two or more urban areas separated by open country. Some enterprises using busses, or rail cars, or perhaps a combination of the two, engage in interurban transport exclusively. Cyclical and other economic influences no doubt affect these three kinds of traffic differently. The occasions for interurban travel differ in nature from those for ordinary municipal travel. But unfortunately no consecutive nationwide statistics of passengers carried distinguish between intracity, suburban, and interurban riders. We are therefore obliged to study the three as a whole. Undoubtedly most of the business covered by the figures is intracity.

Chart 126
Transit Rides, United States, 1917-1940

Shaded periods are reference contractions.

## Patronage and business conditions

In the four reference phases from 1920 to 1926 and in the two from 1932 to 1938, people curtailed their use of transit facilities when business was deteriorating and increased it when business was improving. Although patronage diminished in all three phases between 1926 and 1932, it fell off much more rapidly in 1929-32 than in 1927-29 (Chart 126). Although it rose in 1918-19, the advance was a trifle slower than in 1919-20 (Table 130). On the other hand, the decline in 1927-29 was, on the average, more rapid
than in 1926-27. With this exception, the number of rides conformed positively to the reference chronology from 1918 to 1938.

$\dagger$ 1917-27, estimates for "revenue passengers carried by electric railways" plus "revenue passengers carried by motor buses", statement tentatively revised 1/8/41, transmitted with letter of July 21, 1941 from Edmund J. Murphy, Director of Information Service, American Transit Association. 1926-29 (1927-40 on Chart 126), electric railway estimates from same, plus estimates of 'total revenue passengers" (bus) from Bus Transportation, Feb. 1929, p. 59; Feb. 1931, pp. 54-5; Feb. 1933, pp. 88-9; Feb. 1934, pp. 42-3; Feb. 1936, pp. 64-5; Jan. 1938, pp. 52-3; Jan. 1939, p. 49; Jan. 1940, pp. 46-7; Jan. 1941, pp. 48-9.

The ATA bus figures include only rides on busses of street railway and former street railway companies and their subsidiaries or affiliates. Neither the railway nor the bus data include rides authorized by pay or free transfers.

The BT estimates pertain to the entire motor bus industry. They include rides authorized by pay transfers but data in the Census of Electrical Industries, 1937, Street railways and trolley-bus and motorbus operations, pp. 32-33, suggest that these are less than 2 percent of all bus rides.

The preceding conclusion pertains to the country as a whole. In New York City for which we have monthly data the relation has been less consistent. The business contractions of 1929-33 and 1937-38, and the intervening expansion, it is true, have readily visible equivalents in the number of rides. Between 1908 and 1929, however, there are no clear-cut specific cycles (Chart

$\dagger$ From Table 6.
127). ${ }^{1}$ Indeed the number did not even conform well in this period. Five comparisons count toward positive, 7 toward inverse conformity, with little net result (Table 131). On the other hand, annual data from 1900 to 1910 suggest positive conformity in 4 of 5 instances (Table 132). This is surprising, for we usually expect monthly figures to register business disturbances more sensitively. Making all the comparisons of adjoining phases from 1900 to 1938 that we can, using annual data whenever monthly statistics are not available for both phases, we find that 12 suggest positive, 8 inverse conformity.

${ }^{\mathrm{b}}$ From Table 6.
Cyclical variation small
When specific fluctuations in the number of rides did occur, they were rather mild, much less severe, for example, than those in freight traffic (Tables 133, 134). Even in the great contraction

[^0]1929-32, when ton-miles decreased 55 percent, riding in New York subways, street cars, and busses diminished only 16 percent.

Chart 128
Domestic Disappearance of Gasoline, August 1917-December 1928, and of • Motor Fuel, January 1929-December 1938

## HIGHWAY TRAFFIC

## Reflection of business conditions recent

There are no sufficiently continuous statistics of any kind for the commercial motor freight industry: the enterprises that carry the goods of others for hire on streets and roads. We can, however, form some notion of cyclical variation in the collective highway operations of all classes of users-private motorists, firms hauling their own goods, commercial carriers of property and personsfrom the data on domestic disappearance (approximately, consumption) of motor fuel. From 1917 to 1931 there is little evidence of such variation. No specific cycles are discernible (Chart 128). ${ }^{2}$ From 1918 to 1929 disappearance of fuel did not even conform to cycles in the economy at large; three comparisons count one way, four, the other (Table 135). But the great contraction of 1929-33

[^1]made a clear impress: for a long time (two years) in the form of a mere flattening of the curve, but eventually in an actual decline. And the two subsequent reference phases have obvious analogues in fuel consumption.

## Use of vehicles far more stable than their production

The aggregate number of miles all care and truole womo drivom. presumably fluctuated in somewhat the same way as their consumption of gasoline. There must have been a striking contrast between the amount of use vehicles received and their production.
 tions (Table 136); it declined even during the contractions in which use increased. This was true of the production of commercial vehicles also. When, after 1929, specific variations in
utilization did finally appear, they were much slighter than those in production. The figures for fuel consumption are $-11,46$, and -3 percent (Table 137). The corresponding figures for the output of passenger cars are $-78,306$, and -60 ; of motor trucks, -79 , 403 , and -57 .

The sharp contractions in production had little effect on the stock of vehicles in use. The number of passenger cars registered at the end of the year increased without interruption from 1895
to 1929, as did the number of trucks from 1904 to 1930. Cyclical fluctuations in registration did occur later, but in amplitude they resembled the changes in the consumption of gasoline more nearly than those in the production of vehicles (Table 138).

$\dagger$ Automobile Manufacturers Association, Automobile Facts and Figures, 1944-45, p. 50. Reported or estimated data in this source go back to 1895 (cars) and 1904 (trucks).

The unbroken growth of registrations during the reference phases before 1929-32 helps to explain the continuous rise of aggregate gasoline consumption in those phases. The latter rise does not necessarily mean that individual operators of motor vehicles typically increased their use of gasoline even when business conditions were becoming worse. Since the number of vehicles and presumably the number of owners grew, consumption by new owners and by multiple-vehicle owners who added to their fleets may have outweighed a decline in the quantity used by those who, at most, retained or replaced the cars and trucks they had at the beginning of business contraction. The majority of owners, it would seem, did curtail their use of gasoline in 1920-21 and 192324 , when consumption per vehicle diminished (Table 139). However, the specific contractions in the quantity per vehicle, and the specific expansions too, were very mild during the entire period 1921-38.

P or T indicates specific peak or trough.

- Bureau of Mines, Minerals Yearbook, 1937, p. 1,009; 1940, p. 941.
${ }^{\text {b }}$ Each barrel reported only by first line to handle it. ICC Bureau of Transport Economics and Statistics, A Review of Statistics of Oil Pipe Lines, 1921-1941, (Statement 4280, mimeographed, 1942), p. 40. Not available before 1931.
${ }^{-}$A barrel transported consecutively by two lines would be counted twice. Data from Statistics of Railways. Not available before 1925; figures after 1934 apparently not comparable.

PIPE LINES
The cyciical history of pipe line traffic, in the brief period through which wide unce it, resemisies inat of petroleum production, which tended to increase its relative importance in the national economy during expansion and contraction alike (Table 140). Neither showed any diminntion enorecnonrinor to the we....... contraction of y26-27, aithough outpü faitied to rise from 19\%4 to 1928. In comparison with total rail and waterborne traffic, both declined only moderately in the initial phase of the great depression (cf. Table 141). In 1937 each attained a level far above its
previous peak. ${ }^{3}$ The decreases in 1937-38 were again relatively small.

Cbart 129
Tons Carried by Water, Selected Domestic Trades, 1920-1943

Shaded periods are reference contractions.

## WATER TRANSPORT

The two major kinds of domestic'waterborne traffic-movement on the Great Lakes and coastwise shipments-present something of a contrast (Chart 129, Table 141). Iron ore is usually a large part of Lake tonnage. As one might expect from the instability of steel production, ore shipments passed through violent cyclical fluctuations, conforming closely to the reference chronology. Although other commodities the output of which is more stable are carried in large quantities, percentage variations in Great Lakes tonnage as a whole exceeded those in the corresponding national totals, including coastwise traffic. Ton-miles of movement on the Lakes likewise fluctuated violently, and since they account for a very large part of ton-miles on all inland waterways, so did the latter (Chart 130). ${ }^{4}$

Petroleum and its derivatives are an important component of coastwise traffic, although not as important as ore on the Lakes. This oil tonnage, like the volume flowing through pipe lines, reflected the growing relative importance of petroleum in the economy. The analogue of the 1926-27 reference contraction was mild and belated. The contraction in 1937-38 was small. The 1937 peak greatly overtopped 1929 (ore and total Lake traffic failed to regain their 1929 levels). All these features were duplicated in total coastwise tonnage. The 1920-21, 1923-24, and 192932 contractions were also mild in comparison with those in the national waterborne total. Peaks before 1937 regularly surpassed their predecessors.

Chart 130
Ton-miles on Great Lakes and on All Inland Waterways, 1925-1943

Fluctuations in total domestic waterborne commerce, which corresponded fairly closely to the reference cycles (Chart 131), were not extremely large or small. They did not differ greatly from those in railway freight traffic (Table 141). In general, water tonnage grew by a larger percentage than rail tonnage in expansion, diminished less in contraction. The comparisons suggest that noncyclical influences (improvement of waterways, rapid growth in the production of oil and perhaps of other commodities especially suited to water transport, etc.) tended to stimulate
water relatively to rail movement in both kinds of phase. They do not indicate a difference in sensitivity to cyclical business disturbances. ${ }^{5}$

Chart 131
Tons Carried by Water, All Domestic Commerce, 1920-1943

Shaded periods are reference contractions.
Estimates of water traffic and employment by Harold Barger and J. M. Gould suggest that the productivity of labor engaged in water transport, like that of railroad labor, tends to rise with expansion and fall with contraction of traffic. ${ }^{6}$

For the nation as a whole water traffic statistics begin only in 1920. We do have figures going much farther back for the canals of New York, including the Erie (now the Barge) Canal, once of great importance. Specific cycles in this tonnage do not match the reference cycles very well (Chart 132). But the data conform

positively to the reference chronology (Table 142). The relation is not very close, however; 34 comparisons rate positive, 15 inverse. The unopposed cases ( 34 minus 15) are only 39 percent of been large, and farm production is not associated as closeiy as industrial production with changes in business conditions. When we deduct products of agriculture from the total, the conformity
becomes closer. The number of unopposed cases ( 39 minus 10) becomes 59 percent of the total. ${ }^{7}$

## AVIATION

Commercial air transport was in its infancy at the beginning of the 1933-38 business cycle. Between the initial and final trough the number of miles traveled by patrons of scheduled air services quadrupled; 1938 in turn looks small in comparison with later years (Chart 133). ${ }^{8}$ Obviously, the technology and relative cost position of the airlines, and the attractiveness of their service to travelers, were improving in both expansion and contraction. 'Traffic continued to increase in 1937-38. The rate of growth, however, was not as rapid as in 1932-37, although the difference is small (Table 143).

[^5]
[^0]:    ${ }^{1}$ Data from annual reports of N. Y. State Public Service Commission for the First cated beiow. Suopway, eievated, and street car passengers included throughout. Bus passengers excluded, 1907-29 segment; included, 1927-41. Data for busses compiled by the NBER from reports of individual companies in files of the Transit Commission, January 1927-June 1935; taken from worksheets of the Commission, July-December 1935.

[^1]:    ${ }_{2}$ Sources are as indicated in Table 135.

[^2]:    ${ }^{\text {a }}$ From Survey of Current Business, June 1927, p. 22, and Automobiles (Bureau of Census, mimeographed) various issues. Three-month average; date of level is middle month.
    b June 1924 was almost as low.

[^3]:    ${ }^{3}$ We have no directly comparable figures for traffic. Barrels originated are roughly half of barrels transported. About $600,000,000$ barrels must therefore have originated in 1930. For 1937 the figure is $948,000,000$.
    ${ }^{4}$ Data from Commercial Statistics, 1925-43. None before 1925. Inland excludes coastwise, for which no ton-mile data are available.

[^4]:    ${ }^{5}$ None of the date reviewed tell ws amything abouic the fortunes of the commerciai water transport industry. A large part of the traffic, especially of ore and petroleum, secancer vose iron ore moving over the Great Lakes in the four months May to August 1944 shipped 11.9 percent of it in their own vessels and 37.0 percent in those of subsidiary and related companies. The oil industry poured 66.9 percent of its coast-
    
     affiliates. (C. S. Morgan, Problems in the Kegulation of Domestic Transportation by Water, Report in Ex Parte No. 165, published by the ICC, 1946, pp. 48, 61.)
    ${ }^{6}$ Their indexes of output, employment, and employment per unit (the inverse of productivity) are published in Solomon Fabricant, Labor Savings in American Industry, 1899-1939, NBER Occasional Paper 23, (Nov. 1945), p. 51.

[^5]:    ${ }^{7}$ Most of the differences, with respect to the kind of conformity suggested, between tonnage including and tonnage excluding farm products were, however, confined to two short periods. One occurred in the 1840's, all four others in the 1890's.
    ${ }^{8}$ Data from Department of Commerce, Air Commerce Bulletin, and Civil Aeronautics Administration, Civil Aeronautics Journal.
