When did the dollar overtake sterling as the leading international currency? Evidence from the bond markets

Livia Chitu, Barry Eichengreen, and Arnaud J. Mehl

NBER Working Paper No. 18097

May 2012

JEL No. F30,N20

ABSTRACT

This paper offers new evidence on the emergence of the dollar as the leading international currency, focusing on its role as currency of denomination in global bond markets. We show that the dollar overtook sterling much earlier than commonly supposed, as early as in 1929. Financial market development appears to have been the main factor helping the dollar to surmount sterling's head start. The finding that a shift from a unipolar to a multipolar international monetary and financial system has happened before suggests that it can happen again. That the shift occurred earlier than commonly believed suggests that the advantages of incumbency are not all they are cracked up to be. And that financial deepening was a key determinant of the dollar's emergence points to the challenges facing currencies aspiring to international status.

1. Introduction

The global economic and financial crisis has lent new impetus to discussions of the future of the international monetary and financial system. Policy makers in countries like China and Russia have openly questioned the viability of the current dollar-based global system. Some advocate moving to a multipolar system in which the dollar shares its international currency role with the euro, the Chinese yuan and/or the IMF's Special Drawing Rights. At the Cannes Summit of November 2011, G20 Leaders committed to taking "concrete steps" to ensure that the international monetary system reflects "the changing equilibrium and the emergence of new international currencies".¹

Others expect this change to develop more spontaneously; they see it as a natural result of the declining economic and financial dominance of the United States and the increasingly multipolar nature of the global economy, together with the advent of the euro and rapid internationalization of the yuan (e.g. Angeloni et al., 2011; Bini Smaghi, 2011a and 2011b; Constâncio, 2011; Dorrucchi and McKay, 2011; Eichengreen, 2011; Fratzscher and Mehl, 2011; Subramanian, 2011).

Sceptics object that prospect of a shift to a multipolar monetary and financial system is in fact remote; if it occurs, such a transition will take many decades to complete (Kenen, 2011; Frankel, 2011). The view that a shift to a multipolar system is unlikely to occur rapidly is rooted in theoretical models where international currency status is characterized by network externalities giving rise to lock-in and inertia, which benefit the incumbent (see e.g. Krugman, 1980; Krugman, 1984; Matsuyama, Kiyotaki and Matsui, 1993; Zhou, 1997; Hartmann, 1998; and Rey, 2001).

These models rest, in turn, on a conventional historical narrative, epitomized by Triffin (1960), according to which it took between 30 to 70 years, depending on the aspects of economic and international currency status considered, from when the United States overtook Britain as the leading economic and commercial power and when the dollar overtook sterling as the dominant international currency. The US, it is observed, surpassed Britain in terms of absolute economic size already in the 1870s. It became the leading commercial power, gauged by the value of foreign trade, already in 1913. It was the leading creditor nation by the conclusion of World War I. And yet sterling remained the dominant international currency not simply during this period but also throughout the interwar years, according to the conventional narrative, and even for a brief period after World War II.

Recent studies, referred to by Frankel (2011) as the "new view," have challenged this conventional account. Eichengreen and Flandreau (2009), relying on new data on the currency composition of global foreign exchange reserves, show that the dollar in fact overtook sterling as leading reserve currency already in the mid-1920s – that is to say, more than two decades prior to the date assumed by previous scholars.

¹ See the G20 Leaders' *Final declaration* at the Cannes Summit, 3-4 November 2011.

Eichengreen and Flandreau's "new view" also challenges broader implications of the conventional narrative. First, it suggests that inertia and the advantages of incumbency are not all they are cracked up to be. Second, it challenges the notion that there is room for only one international currency in the global system. Eichengreen and Flandreau show, to the contrary, that sterling and the dollar accounted for roughly equal shares of global foreign exchange reserves throughout the 1920s. Third, the new view challenges the presumption that dominance, once lost, is gone forever. Eichengreen and Flandreau's data indicate that sterling re-took the lead from the dollar for a brief period after 1931. This reinforces the point that the advantages of incumbency in the competition for reserve currency status may be less than commonly supposed.

In a companion piece, Eichengreen and Flandreau (2010) show that what was true of reserve currencies was true also of the use of currencies for financing international trade. The dollar overtook sterling as the leading form of trade credit (as the currency of denomination for what were known as "trade acceptances" or "bankers' acceptances") already in the mid-1920s, not only after World War II. The US achieved this from a standing start – that is to say, despite the fact that dollar-denominated trade credits had been virtually unknown as recently as 1914. Both market forces (financial market development) and policy support (with the Federal Reserve System as a market maker in the New York market for bankers' acceptances) were instrumental in helping the dollar rival and overtake sterling. That said, both New York and London, and both the dollar and sterling, remained consequential sources of trade credit in the 1920s. This again challenges the notion of international currency competition as a winner-take-all game.

Some critics have questioned the new view. Ghosh, Ostry and Tsangarides (2011) suggest that the interwar gold standard was special in that gold, not foreign exchange, was the dominant reserve asset, accounting for some two thirds of international reserves. The fact that gold played a large monetary role then but plays only a small one today may limit the inferences about prospective changes in international currency status that can be drawn from this earlier experience, in other words. Forbes (2012) suggests that, compared to the past, international financial transactions may play a larger role in driving the decision of which unit or units to use internationally, while merchandise transactions and the importance of a currency and market as a source of trade credit play a correspondingly smaller one. Thus, inferences about the future are less convincing insofar as they are drawn from the past behaviour of trade credits and not from the use of currencies in international financial transactions.

In this paper we address these objections and complete the story. We provide new evidence from the interwar years on the use of the leading international currencies, sterling and the dollar, in international financial transactions. This sheds light on a third dimension of international currency status, along with the use of a currency for trade-related transactions and as international reserves, namely the use of currencies as vehicles for international financing. We focus on the international bond market, bonds being the principal instrument for foreign lending and borrowing in this earlier era prior to the advent of syndicated bank lending.² Looking at yet an

² As explained in *inter alia* Eichengreen and Portes (1989).

additional aspect of international currency competition is useful for establishing the generality (or otherwise) of the so-called “new view.” In addition, because international bonds were typically denominated in national currencies and not gold, the objection that competition between gold and currencies complicates the effort to draw inferences for the future is less telling in this context.³

We employ data on the currency denomination of foreign public debt for 33 countries in the period 1914-1946. We focus on bonds issued in foreign markets (“international bonds”) because these were only rarely denominated in the issuer’s own currency; they were denominated in international currencies so as to appeal to international investors. It is thus the denomination of these foreign bonds that shed light on international currency use.⁴

Our analysis supports the new view in that the dollar had a share almost equal to that of sterling as a currency of denomination for international bonds already in the interwar years. When excluding the Commonwealth countries, which were heavily inclined towards sterling issuance due to their dominion status, the dollar overtook sterling as early as 1929.

Our results further call into question two other tenets of the conventional narrative. While sterling lost its pre-eminence in 1929 (again, abstracting from the Commonwealth countries), it subsequently ran neck and neck with the dollar as the dominant currency of denomination for international bonds at least for a brief period. This is at odds with the conventional view that dominance, once lost, is gone forever. It is, however, consistent with the findings of Eichengreen and Flandreau for foreign exchange reserves and merchandise: they find that with the liquidation of central bank holdings of dollars starting in 1931 sterling regained its lead as a reserve currency for at least a brief period; they similarly find that the market in dollar trade acceptances collapsed and that the dollar gave back ground to sterling with the financial crisis in the United States in 1931-33.

Second, much of the 1920s and the 1930s saw the use of both sterling and the dollar as currencies of denomination in international debt markets. This was a bipolar rather than a unipolar currency system. This finding is at odds with the presumption that there is room for only one dominant international currency in the market.

Finally, our results point to financial development as the main factor enabling the dollar to overcome sterling’s incumbency advantage. Its impact dwarfed those of country size and the monetary policy-cum-exchange rate regime. We allow also for incumbency effects and show how these were swiftly overcome by financial development.

These findings are relevant to discussions of the future of the international monetary system. They suggest that a shift from a dollar-based system to a

³ There were some so-called gold bonds (gold-indexed bonds or bonds containing clauses specifying that they were to be redeemed in national currencies of constant gold content). We discuss these further below.

⁴ The reluctance of foreign investors to purchase bonds denominated in the currency of the issuer in more recent periods has similarly been emphasized in the literature on “original sin” (Eichengreen and Hausmann, 2005).

multipolar system is not impossible; that this could occur sooner than commonly believed; and that financial deepening will be a key determinant of how and when additional units strengthen their international currency status.

Contemporary data on the currency of denomination of international bonds is further consistent with the existence of this kind of shift. The share of the euro in the stock of international debt securities increased to some 30% in the 2000s from approximately 20% in the 1990s (proxied by the share of legacy currencies prior to 1999, net of intra-euro area issuance).⁵ Again, this is inconsistent with the presumption that there is room for only one international currency in the financial domain.

The rest of the paper is structured as follows. Section 2 presents our dataset and section 3 some stylised facts. Section 4 describes our empirical methodology, while section 5 presents the baseline empirical results. Following a discussion of robustness in section 6, section 7 concludes and draws implications for policy and future research.

2. Data

For data on the currency composition of foreign debt we draw on United Nations (1948).⁶ The data it contains were gathered by statisticians employed by the League of Nations, the UN's predecessor, and by the UN itself, drawing on official national sources including national accounts and/or budgetary accounts prepared by ministries of finance, annual or special reports of central banks or national statistical institutes, national statistical yearbooks, and so forth. An overview of these primary sources is in Appendix I.

As is also the case with modern debt data, there is always the possibility that the UN data are not strictly comparable across countries.⁷ Some debt floated in foreign financial centers may in fact be purchased by domestic residents. Some national statistical agencies may include with foreign debt domestically issued securities purchased by foreign investors. The authors of the UN compendium attempted to adjust for these problems insofar as possible.⁸ But what is key for our

⁵ See Appendix III as well as ECB (various issues) and Detken and Hartmann (2000) and (2002).

⁶ It also contains data on outstanding amounts of *domestic* public debt in some 50 countries during the interwar period, compiled from national sources, data that have been used by Reinhart and Rogoff (2008a, 2008b, 2009a, 2009b, 2010) and Reinhart (2010) and in subsequent work on public debt developments in the very long run (e.g. Ali Abbas et al. 2011; Fratzscher, Mehl and Vansteenkiste, 2011). Data on domestic public debt were not broken down by currency, which is why we focus in the paper on foreign public debt.

⁷ For an example of a modern debt-data compendium, see World Bank (various dates).

⁸ As the authors of the volume observed (p. 8) "The division of the debt into domestic and foreign is not always based on the same criteria. In a number of countries, the distinction between domestic and foreign debt is made according to the currency in which the debt is expressed; in others, according to the place where the debt was contracted – *i.e.*, abroad or at home; in others still, according to the residence of the creditor: in the latter case, foreign bonds repurchased by residents of the home country are considered domestic debt, as in Sweden." Similarly, in the case of Norway, it is specified that (United Nations, 1948, p. 107): "According to an estimate by the Bank of Norway, the following amounts of loans raised abroad were owned by Norwegians at the end of 1940..." Similarly, in the case of Uruguay, it is reported that (*ibid.*, p. 154) "Domestic debt includes also the so-called

purpose, which is to gauge the importance of sterling, the dollar and other currencies as vehicles for international financial transactions, is that the public debt categorized as foreign by the UN is distinguished by currency of denomination.⁹ Evidently, the UN applied consistent criteria when categorizing countries' foreign debts by their currency of denomination. Each foreign debt issue was categorized by "the original currencies in which it was raised." The authors distinguish the currency of issuance from the currency of the country in which the bonds were issued. They account for the fact that not every foreign bond issued in London was denominated in sterling, that the currency in which the bond was issued was not always the same as the currency in which it was redeemed, and that both the currency of issuance and currency of redemption could differ from the currency of the country where it was issued (for instance, a bond issued in French francs in London might be payable in dollars).¹⁰

We digitized the UN data on foreign public debt for 33 countries (including five Commonwealth countries) in three continents (Asia, Europe and America): Argentina, Australia, Austria, Belgium, Bolivia, Brazil, Canada, Chile, Colombia, Costa Rica, Cuba, Denmark, Dominican Republic, Finland, France, Guatemala, Haiti, Honduras, India, Japan, New Zealand, Nicaragua, Norway, Panama, Peru, Poland, Portugal, Romania, Siam, South Africa, Switzerland, Turkey and Uruguay. A few countries (e.g. Italy) that provide data on their overall stock of foreign debt but not on its currency composition were necessarily excluded from the sample. A detailed description of the data is in Appendix II.¹¹

Data are annual and available from 1914 to 1946.¹² Some 14-24 countries report data between 1914 and 1927 (see Figure 1); approximately 30 countries report data between 1928 and 1939; and 19-27 countries report data between 1940 and 1945.

'International Debt' consisting of two Brazilian issues, but which are payable in Uruguayan pesos and are held in Uruguay".

⁹ In addition, since we exclusively consider non-US and non-UK debt, it is always the international financing role of sterling or the dollar that is captured by our data.

¹⁰ An example of this awareness is their discussion of Norway. As the UN authors explain (p. 107), "The loans raised [by Norway] in France were originally issued in francs [*i.e. the currency of the country in which the bond was issued as well as its currency of issuance*], but are also payable in several currencies at fixed rates of exchange, including sterling at 25.25 francs = 1 sterling [*i.e. currency in which the bond was redeemed*]. After the devaluation of the French Franc in 1928, these bonds were paid, beginning with 1933, in sterling in Paris, rather than in French francs." The UN authors take these differences into account and adjust the data correspondingly: "The outstanding amounts have therefore, up to 1932 inclusive, been converted at par rates of exchange, but beginning with 1933 the francs have been converted in sterling at 25.25." In cases where currency of denomination was not specified as e.g. Canada, Australia, New Zealand and South Africa, for which we could gather from the UN volume security-by-security information as to whether debt was "payable", "redeemable" or "due" in London or in New York, we determined this from other sources. Where it was not possible to determine this on the basis of other sources, we excluded the country.

¹¹ Data on commercial (*i.e.* private) debt (denominated in gold francs) are also available for France. Such private debt accounts for approximately 15% of France's total foreign debt. Since we do not have comparable private debt data for the other countries in our sample, we exclude France's commercial debt from our analysis.

¹² Subject to missing observations (typically during World War I and its immediate aftermath and during World War II).

Alongside sterling, the dollar, the French franc, the Swiss franc and the German mark, foreign public debt was issued in 16 other currencies. These include the Austrian schilling, Belgian franc, Canadian dollar, Czechoslovak crown, Danish crown, Dutch florin, Dutch gulden, Italian lira, Norwegian crown, Scandinavian crown, Spanish peseta, Swedish crown, Argentinean peso, Romanian lei.¹³ While around one-third of the countries in our sample (e.g. Cuba, Dominican Republic, Haiti, India, New Zealand, Panama, Portugal, South Africa, Switzerland and Siam) had foreign debt in only one currency (either sterling or dollars), others had foreign debt in ten or more currencies. Romania had foreign debt in 14.

Debt denominated in some of these minor currencies was occasionally denominated in currency units of constant gold content. Thus, the data set includes foreign debt denominated in Argentine gold pesos, Austrian gold crowns, Austrian gold florins, French gold francs, Italian gold lire and Romanian gold lei. Argentina, Austria, France and Romania had been off the gold standard for extended periods and/or suffered high inflations, helping us to understand the practice.¹⁴ However, the value of foreign bonds denominated in currencies of constant gold content was relatively small, namely in the order of 3% of the global total stock. There appear to have been almost no dollar or sterling loans of constant gold content.¹⁵ Turkey issued such bonds between 1933-1934 and 1938-1939 but in negligible amounts (some \$6-9 million).

We take the book value of outstanding amounts in different currencies and convert them to US dollars using end-of-year market exchange rates.¹⁶ Debt in gold currency is converted to US dollars using the exchange rate under the gold standard that is nearest to the year when such debt was issued. For instance, Brazil's debt in gold francs (issued in 1914) is converted to its equivalent US dollar amount using the Franc Germinal 1914 parity (5.095 gold francs per US dollar).¹⁷

Following standard practice in the literature, we use currency shares at current exchange rates in our empirical model. This allows us to compare our results with those of earlier studies. However, to take into account the impact of devaluations (like that of sterling in 1931 and the dollar in 1933) and valuation effects, we also calculate currency shares at constant exchange rates, which we consider in robustness checks.¹⁸

¹³ Names could change over time. For instance, the Austro-Hungarian "gulden" was replaced by the crown ("krone") in 1892 as part of the introduction of the gold standard. However, the name "florin" was used on Austrian coins, while "forint" was used on post-1867 Hungarian banknotes and coins.

¹⁴ Borchard (1951) describes this in more detail.

¹⁵ There were, however, gold clauses specifying payment in dollars of constant gold content in U.S. treasury liabilities issued domestically in this period. Those gold clauses were famously thrown out by the U.S. Supreme Court following the 1933 devaluation of the dollar (Kroszner, 1999).

¹⁶ Taken from the UN volume, *Global Financial Data* (GFD) and the *Measuring Worth* database.

¹⁷ There is no need to exclude from the aggregate share of debt issued in gold the amount of debt issued in dollars or sterling of constant gold content to correct for potential downward biases in the aggregate dollar and sterling shares between 1919 to 1933, since no country issued debt denominated in dollars or sterling of constant gold content in those years.

¹⁸ Considering the evolution of currency shares in both constant and current market exchange rates is similarly the practice in studies of the currency composition of foreign exchange reserves (e.g. Truman and Wong, 2006; ECB (various issues)).

Another issue is the treatment of war-related debts. France is the most notable case: between 80 and 90% of its foreign public debt was owed to allied governments and incurred during World War I. Moreover, France's foreign public debt, at some \$6-7 billion, is by far the largest in our sample, and equivalent to over a third of our 33 countries' total stock of foreign public debt. It will therefore be important to check for the sensitivity of our results to the (ex)inclusion of France (from) in the sample.

A further distinction is between the fiscal and calendar years, which do not always coincide.¹⁹ A few countries have fiscal years that start on 1 April of year t and end on 31 March of year $t + 1$. There are even some countries (e.g. Brazil, France, Romania and Poland) that changed from calendar to fiscal year at some point in our sample. We follow the UN statisticians' convention by assigning data for fiscal year 1 April t to 31 March $t + 1$ to calendar year $t + 1$.²⁰

3. Stylized facts

We start with an overview of the evidence that can be immediately gained from these data. By 1929, roughly the mid-point of our sample, our 33 countries owed more than \$17 billion of foreign public debt, about double the amount owed in both 1920 and 1939 (Figure 2). This amount corresponded to about 4% of world GDP. It is a bit higher in magnitude than the amount of global reserves (in gold and foreign exchange, with 24 countries) estimated by Eichengreen and Flandreau (2009) for that year, namely about \$10 billion. By comparison, as of end-2010, the stock of international debt securities accounted for 17% of world GDP and 114% of world reserves.²¹

Of these \$17 billion, some \$10 billion was sterling debt (also equivalent to almost 50% of UK GDP) and another \$7 billion was dollar debt (also equivalent to roughly 7% of US GDP). The shares of both currencies were substantial. This confirms the insight of the "new view" that there is room for more than one international financing currency at any point in time.

Sterling and the dollar together accounted for about 97% of global foreign public debt. Other currencies, such as the French franc, the Swiss franc, the German mark and the Dutch guilder, were largely irrelevant, this despite the fact that the French and German economies were substantial in size.²² The absence of the French franc is notable, given the efforts of French officials to elevate Paris to the status of an international financial centre and secure for the franc an international role (Meyers, 1936). This reinforces Eichengreen and Flandreau's finding using data on the currency composition of foreign exchange reserves, which were heavily

¹⁹ As is the case today in most countries.

²⁰ Two exceptions were France, Poland and Romania, where we assigned the data to calendar year t so as to avoid gaps in the time series.

²¹ According to data from the ECB's *Review of the international role of the euro* (July 2011 edition) and the International Monetary Fund's World Economic Outlook Database (September 2011 edition).

²² In the early 1930s, the combined share of currencies other than sterling and the dollar reached a peak of almost 10%, however.

dominated by sterling and dollars and where the French franc similarly did not provide a meaningful alternative.

As noted above, securities indexed to gold accounted for a very small share of international bonds (about 1% in 1929).

There are also marked differences in the regional origin of foreign public debt denominated in sterling and dollars (see Figures 3 and 4). Almost 80% of dollar-denominated debt was owed by Europe. Of that amount, the main debtor was, by a large margin, France, which alone accounted for almost 60% of global foreign public debt owed in US dollars. This reflected France's heavy involvement in World War I since, as mentioned above, the largest share of its debt was held by allied governments. US loans to the French government, first through the agency of US banks and then by the US government itself, amounted to just over \$4 billion when converted into long-term bonds in the early 1920s.²³ Most of the remainder was owed by Latin America (where four countries, Cuba, Dominican Republic, Haiti and Panama, issued foreign public debt exclusively in dollars). This reflected the strong economic and financial ties that the U.S. developed with the region since the turn of the century and, especially, during and after World War I (Mitchener and Weidenmeier, 2005). The rest was owed by two Commonwealth countries (Australia and especially Canada) and Japan, which borrowed in the US as early as 1904-5 to finance its war with Russia and returned to the market in the 1920s.²⁴

The bulk of sterling-denominated debt (about 40%) was owed by the Commonwealth countries, in line with their strong political as well as economic ties to the UK. A further 40% was owed by Europe. France was again the main European originator, accounting for a third of global foreign public debt denominated in sterling. Asia (i.e. Japan and Siam, with the latter one issuing debt exclusively in sterling) accounted for around 5% of global foreign public debt in sterling, while Latin America (Argentina, Brazil, Chile, Bolivia, Costa Rica, Honduras, Guatemala, Nicaragua, Peru and Uruguay) accounted for a further 9%.²⁵

When did the dollar surpass sterling as leading currency of denomination of international bonds? Figure 5a shows the breakdown of global foreign public debt at market exchange rates when the sample includes all 33 countries. By 1931, the share of the dollar (45%) was almost equal to that of sterling (51%).

Including our five Commonwealth countries in the aggregates may bias the results, however, due to their strong political links with the UK, which constrained

²³ Amounts borrowed from the UK by the French government were slightly smaller (Moulton and Pasvolsky 1926, p. 45). The relatively even breakdown of French debt between sterling and dollars in the 1920s is evident in Figure 7 below.

²⁴ Of \$245 million of war loans floated abroad by the Japanese government in 1904-5, \$192 billion were sold in the United States (Lewis 1938, p. 340). It appears that, unlike Japanese borrowing in New York in the 1920s, these earlier bonds were not dollar denominated.

²⁵ That India, as a British colony, should have issued debt exclusively in London is unsurprising. While the Thais successfully maintained their independence by playing the British and French colonialists off against one another, their dependence on the London market (with their foreign debt consisting "entirely of sterling obligations", as stressed in UN (1948, p. 129) is evidence of the continuing importance of sterling and secondary status of the French franc in international bond markets (see above).

their tendency to issue debt in currencies other than sterling.²⁶ Indeed, the picture changes dramatically when one excludes the Commonwealth countries, as in Figure 5b. The cross-over date is now 1929. Sterling's lead is largest in 1924, although the dollar's share of the market is already substantial. The second half of the 1920s then shows the dollar closing the gap; this was the period marked by "the scramble for 'investment opportunities'" (Lewis, 1938, p. 376 – the quotation marks around "investment opportunities" are hers) and when British authorities, concerned with the weakness of the balance of payments, used moral suasion and controls in an effort to restrain long-term foreign lending (Moggridge, 1971).

Figure 5b is strikingly similar to that obtained by Eichengreen and Flandreau (2009) using their data on reserve composition.²⁷ It is inconsistent with the conventional wisdom that sterling remained the dominant currency throughout the interwar period despite the fact that the US had long since overtaken the UK as the main economic, commercial and financial global power.

Sterling then regained market share after 1933 and again ran neck and neck with the dollar at the end of the decade. U.S. experience with foreign public debt in this period was unhappy; some two-thirds of outstanding issues lapsed into default, roughly double the share of sterling-denominated debt (Winkler, 1933). This reflected a combination of factors: bonds issued in dollars appear to have been more marginal credits; U.S. underwriters were less experienced; sterling-denominated bonds issued by members of the British Commonwealth and Empire were faithfully serviced all through the 1930s (Mintz, 1951, Eichengreen and Portes, 1990). But whatever the explanation, the relatively widespread defaults on dollar-denominated debts demoralized the New York market and limited foreign issuance there. The Johnson Act of 1934 then prohibited governments in default on their sovereign debts from marketing new loans in the United States.²⁸

History can be messy; this is certainly true of the 1930s. But the fact that a variety of special factors caused the lead of the dollar over sterling as a currency of denomination for international bonds to narrow temporarily does not change our central conclusion that the greenback had emerged as a major vehicle for long-term foreign lending already in the 1920s. Indeed, it reinforces the point that fortunes can change quickly and that the advantages of incumbency tend to be overstated.

How sensitive are these conclusions to alternative methods? The finding of a sterling-dollar duopoly carries over if we calculate currency shares at constant rather than current exchange rates in order to control for valuation effects due to the devaluation of sterling in 1931 and of the dollar in 1933.²⁹ However, the dollar no longer comes close to surpassing sterling in 1931, since we have eliminated the devaluation of sterling-denominated claims in September of that year; still, the

²⁶ The sovereignty of these countries remained indeed subject to limitations at least until the statute of Westminster in 1931, which declared self-governing dominions within the British Empire to be equal.

²⁷ The parallel could reflect the fact that official and private foreign investors respond to similar pecuniary and nonpecuniary incentives. Another interpretation is that central banks hold reserves in part to facilitate intervention in the foreign exchange market, where the relevant foreign exchange market is the one on which domestic issuers depend.

²⁸ But, notwithstanding this setback, the dollar then permanently overtook sterling in the early 1940s. And not only after World War II, as suggested in earlier accounts.

²⁹ We focus on the full sample of 33 countries, unless explicitly stated otherwise.

greenback retains a sizeable share of global bond markets, of about 40% (Figure 6a). The results similarly point to the existence of a sterling-dollar duopoly rates when one excludes France, the largest dollar debtor (Figure 6b).³⁰

Using current exchange rates and unweighted averages to control for the fact that the largest debtors have a disproportionate influence on the aggregates changes things noticeably, however (Figure 6c). By this metric, the dollar overtook sterling already in the mid-1920s.

Likewise, using current exchange rates and weighted (by the size of debt) averages but excluding countries owing debt exclusively in dollar or sterling as well as Commonwealth countries which were so much tilted to sterling issuance for political reasons suggests that the dollar already surpassed sterling in the late 1920s and never gave back its dominant position (see Figure 6d).³¹

Figure 7 shows that already at the time of World War I the dollar was the dominant currency of foreign debt denomination in Belgium, the Dominican Republic, Haiti, Panama, Poland and Switzerland.³² Swiss bonds, for example, were sold in New York as early as 1899.³³ The efforts of New York underwriters to attract foreign borrowers to the U.S. market were actively supported by the State Department, which saw foreign dependence on US lending as a lever for opening foreign markets to American exports. Bolivia, Brazil, Chile, Guatemala, Norway, Peru, Romania and Uruguay steadily increased the share of their foreign currency debt in dollars in the course of the 1920s, this being when American promoters aggressively “search[ed] the world over for foreign borrowers.”³⁴

In just three countries – Austria, Colombia and Finland – did the share of the dollar decline markedly in the interwar years. In Austria this reflected the growing dependence of the government on Paris, the one market that remained open during the early-1930s financial crisis. Finland borrowed in Swedish kronor (for, inter alia, extension of its telephone system) in the 1930s and during World War II. Colombia engaged in a borrowing binge in New York in 1927-28, when it issued two mega-loans in dollars; thereafter its relatively modest borrowings were both in sterling and dollars as well as in French francs in the case of a substantial 1931 loan floated in Paris, bringing down the dollar share of the total. There was similarly some movement by central banks into subsidiary currencies like the French franc and Swedish kronor in the 1930s, when problems affected the markets in dollars and sterling, but it was similarly limited in incidence and magnitude (Eichengreen, 2011).

³⁰ Here we again use market exchange rates.

³¹ Many of these countries borrowing exclusively in one of the two major currencies were members of the British Empire who essentially had no choice. One might argue that in analyzing the choice of vehicle currency for foreign borrowing we should focus exclusively on countries that actually had such a choice points to excluding these cases.

³² And by 1919 in the case of Poland, after it gained independence in 1918.

³³ Lewis (1938), p.337.

³⁴ Lewis (1938), p.377.

4. Econometric specification

We now estimate the determinants of currency shares of foreign public debt. Given that shares are, at any point in time and in any country, bounded between zero and one, we estimate a tobit model. Since our panel has a 3-dimensional structure with country, currency and time dimensions, we account for the possibility of unobservable country, currency and time effects:

$$y_{i,j,t}^* = \alpha_{i,j} + \eta C_j + \beta s_{j,t} + \gamma' \mathbf{X}_{j,t} + \boldsymbol{\theta}' \mathbf{D}_t + \varepsilon_{i,j,t} \quad 1)$$

with

$$y_{i,j,t} = \begin{cases} 1 & \text{if } y_{i,j,t}^* > 1 \\ y_{i,j,t}^* & \text{if } 0 \leq y_{i,j,t}^* \leq 1 \\ 0 & \text{if } y_{i,j,t}^* < 0 \end{cases} \quad 2)$$

where i, j , and t are the country, currency and time dimensions; y is the share of currency j in country i 's foreign public debt in year t ; s is a measure of financial depth; \mathbf{X} is a vector of key other determinants of international currency status (including inertia, size and credibility effects in the baseline specification); \mathbf{D} is a vector of time effects. We reduce the dimensions of our panel from three to two by distinguishing country-currency (subsequently referred to as 'group') and time dimensions. With 33 countries and two currencies, we therefore have 66 groups, and control for unobserved random effects at the group level, denoted α . We control for other unobserved currency effects with a dummy C , which equals one for US dollar observations and 0 otherwise. The estimable parameters are therefore α, η, β together with the vectors γ and $\boldsymbol{\theta}$.

The disturbances are split into unobserved group effects, with variance σ_α^2 , and panel-level effects, with variance σ_ε^2 , which are assumed to be independent. To gauge whether random-effects tobit estimation is required, we calculate the ρ -statistic, which measures the contribution of the variance of the disturbances due to group effects to the total variance of the disturbances:

$$\rho = \frac{\sigma_\alpha^2}{\sigma_\varepsilon^2 + \sigma_\alpha^2}$$

When ρ is close to zero, random-effect tobit estimation is not significantly different from the standard tobit model. Formal comparison between the two models can be achieved by conducting a likelihood-ratio test, where the null hypothesis is that a standard tobit model is better suited than a random-effects tobit model.

Building on the literature on the determinants of currency shares (e.g. Chinn and Frankel 2007, 2008, Frankel 2011), we focus on four categories of explanatory variables. The first of these is network externalities, which is widely emphasized in the earlier literature. An international currency, like a domestic currency, is more useful when others use it. That is to say, a currency used in international debt

markets is more likely to be used in international trade transactions, in foreign exchange trading, as an anchor currency or as a reserve currency, etc. which gives rise to economies of scope.³⁵ This network effect gives rise to inertia or incumbency effects. To capture them we include the lagged value of y in \mathbf{X} .

Our second potential determinant is country size. The currency of an economy with a large share in global output, trade and finance has a “big natural advantage”, to paraphrase Chinn and Frankel (2007). To proxy for such size effects, we use the time-varying shares of US and UK output in global output.³⁶

A third potential determinant is confidence in a currency’s value. An international currency being a store of value, investors will want to know that its value is stable and will not be inflated away. As a proxy for confidence we use contemporaneous inflation, calculated using annual CPI data.³⁷ We also consider a proxy for economic proximity in the robustness checks, namely the share of US (respectively UK) trade in a country’s trade.

Our final potential determinant of currency shares is s , financial depth. Liquidity is widely recognized as an important attribute of the attractiveness of investing in a particular security – or for that matter in a security denominated in a particular currency – and financial development is an important determinant of market liquidity. Financial depth has not been used in previous studies of the determinants of choice of currency of denomination for, inter alia, central bank reserves, although Eichengreen and Flandreau (2010) show that financial depth and development was a key determinant of the rise of dollar-denominated trade credits in the 1920s.³⁸ As our measure of financial development we use bank assets relative to GDP as measured by Schularick and Taylor (forthcoming). This is in the spirit of Eichengreen and Flandreau, who similarly proxy financial development by the asset side of banks’ balance sheets.

5. Baseline empirical results

To benchmark our results with the estimates in the existing literature for the currency composition of foreign exchange reserves in recent historical periods, we first exclude financial deepening from the model and focus on the other core determinants of international currency status: persistence, credibility and country size. Table 1

³⁵ Krugman (1980) first showed how the use of international currencies as vehicles in foreign exchange markets could be subject to tipping points and path dependency, while Krugman (1984) introduced the notion of multiple equilibria in this context. Matsuyama, Kiyotaki and Matsui (1993) considered the issue in the context of random matching games, along with Zhou (1997). Rey (2001) looked at the emergence of multiple equilibria determined by network externalities and international trade patterns. Flandreau and Jobst (2009) also find empirical evidence in favour of persistence in foreign exchange trading data for the late 19th century, but not in favour of pure path dependency and lock-in effects.

³⁶ Calculated using data from the Groningen Growth and Development Centre (founded by Angus Maddison). See <http://www.ggdc.net/databases/hna.htm>.

³⁷ Again taken from GFD.

³⁸ King and Levine (1993) and a large surrounding literature also analyze the impacts of financial deepening, where financial depth is typically proxied by variables such as credit to GDP or money to GDP, and has been found to have strong causal effects on domestic growth.

presents these benchmark results, where the three variables are entered first one-by-one and then together.

Inertia effects are strong, with a point estimate on the lag of currency share of about 0.98. In other words, only about 2% of the adjustment to the long run in international currency shares in global debt markets is estimated to occur in a single year, *ceteris paribus*. This corresponds to a half-life of about 29 years. This estimate is similar in magnitude to the (linear) point estimates of Chinn and Frankel (2007, Table 8.4, p. 303) of 0.90-0.96 using reserve data for 1973-1998.³⁹ It suggests that in order to adequately understand the evolution of currency shares it is important to consider an extended period of time, as we do here.

Credibility also matters, although its effect is smaller. Lower inflation significantly raises the share of the dollar or sterling in countries' foreign public debt, although the impact is small in magnitude. The full model estimate (column 4 of Table 1) suggests that the short run (one year) effect of reducing the inflation rate by 10 percentage points (a large amount by US and UK standards in the 1920s) is associated with an increase in the share of the US dollar (sterling) of slightly less than a percentage point. Again, our estimated coefficient of -0.07 is fairly close to those of Chinn and Frankel (2007), who found (linear) estimates ranging between -0.07 and -0.14.

Country size is also important. The full model estimate suggests that the short run effect (one year) of an increase in the share of the US (UK) economy in global output of 10 percentage points corresponds to an increase in the share of the US dollar (sterling) by roughly one percentage point. The estimated coefficient of 0.12 is strikingly close to that of Chinn and Frankel (2007), whose (linear) estimates range from 0.09 to 0.12.

Columns 5 and 6 report the results for financial deepening. The point estimates for the persistence and credibility effects remain unaltered, while the size effect is larger than before (with an estimated elasticity above unity) and credibility loses statistical significance. Importantly, financial deepening also exerts a significant effect on the share of the US dollar (sterling) in global foreign public debt markets. The full model estimate suggests that in the short run (over one year) an increase in the ratio of banking assets to GDP by 10 percentage points is associated with an increase in the share of the US dollar (sterling) of about three percentage points.

Figure 8 shows the contributions of size, credibility and financial deepening to the change in the average share of the US dollar in foreign public debt between 1918 and 1932. The contributions are calculated using the estimated parameters of the benchmark model (Table 1, column 6). They take into account dynamic effects arising from the persistence introduced by the lagged values of currency shares in the specification. Those dynamics imply that changes in these variables in the current period have an impact on currency shares not just contemporaneously but in the future as well. For each year t between 1919 and 1932 we calculate the contribution

³⁹ Note that they also provide panel logit estimates; we tried to run regressions with this estimator as well, but convergence of the likelihood function to a global maximum was not obtained.

of variable z (i.e. either size, credibility or financial deepening) to the change in the average share of the US dollar (sterling) in global foreign public debt y as $(\sum_{i=0, \dots, \infty} \rho^i \theta dz_{t-i})/dy_t$, where θ is the estimated parameter for z , ρ is the estimated parameter for the lag of y , and $dy_t = y_t - y_{t-1}$. The overall contribution of z to the change in y is then obtained by summing the 14 annual contributions between 1919 and 1932.

Figure 8 shows that financial deepening is by far the most important contributor to the increase in the share of the dollar as a currency of denomination for international bonds between 1918 and 1932, consistent with the findings of Eichengreen and Flandreau (2010) for the market in trade acceptances. With the ratio of US banking assets to GDP rising from 70% to 100% of GDP over the period, the share of the dollar in global foreign public debt would have risen by almost 50 percentage points *ceteris paribus*.⁴⁰ Next in importance is greater credibility due to lower US inflation, although this impact is not statistically significant.⁴¹

Interestingly, country size contributed *negatively* to the rise of the dollar, since the share of the US in global output fell from 30% in 1918 to 22% in 1932, contributing to a decline in the share of the US dollar of 30 percentage points *ceteris paribus*.

Figure 9 shows similarly estimated contributions for sterling. Here too financial deepening had a positive impact. But country size is the most important factor explaining the fall in the average share of sterling between 1918 and 1932, with the share of the UK in global output falling from 13% in 1918 to 8% in 1932.⁴² This is consistent with the large literature emphasizing how slow growth and high unemployment handicapped Britain's efforts to maintain its financial pre-eminence and undermined the role of sterling in the 1920s (Chandler, 1958; Sayers, 1976).

If one conducts a similar exercise for the period 1932-1939, during which the average share of the US dollar in foreign public debt declined by about ten percentage points, it is again financial depth (in this period financial retrenchment) that contributes most (see Figure 10). Over that period, the ratio of bank assets to US GDP fell by nearly 20 percent of GDP as a result of the bank failures of the Great Depression.⁴³

In sum, we can explain a significant fraction of the change in currency shares in global bond markets in the 1920s and 1930s. Financial development in the United States is the most important determinant of the dollar's rise in the 1920s, while

⁴⁰ Arithmetically, the bank-asset ratio continues increasing in the United States through 1931-32 despite the fact that bank assets decline (GDP declines faster). After that, however, the trend reverses.

⁴¹ There was indeed marked regime shifts between 1918-1919, when the US had double-digit inflation, 1921-22, when it experienced double-digit deflation, and the remainder of the 1920s, when prices were broadly stable.

⁴² To be more precise, financial deepening is the single most important *identified* contributor to the decline in the share of sterling, given that the contribution of the residual is even larger in absolute magnitude.

⁴³ As an alternative hypothesis, one could suggest that it is the dollar's departure from the gold standard that led to the decline in its share of global foreign public debt. This is unlikely to be the case, however. Sterling left the gold standard two years earlier than the dollar, but its share did not fall and actually increased throughout the 1930s.

economic stagnation leading to a decline in relative country size is the most important factor in sterling's decline.

6. Robustness

Table 2 examines the robustness of the results to alternative estimation methods, including a panel tobit estimator without time effects (column 1), a linear random effect estimator (column 2), as well as a linear fixed effect estimator (column 3) with errors robust to heteroskedasticity and clustered heterogeneity for both linear estimators (to explicitly control for possible residual correlation between country-dollar and country-sterling observations in each year). The results are very close to our baseline estimates both in terms of statistical significance and economic magnitude (with the exception of credibility, which again loses statistical significance).

One could also argue that the interpretation of the lagged dependent variable in terms of inertia is problematic, insofar as the latter is simply picking up persistent error terms. The combination of serially correlated errors and the lagged dependent variable also introduces the possibility of biased coefficient estimates due to correlation between the lagged variable and the error term.

One way to deal with this problem is to instrument the lagged dependent variable with its second lag and the first lags of the independent variables (see e.g. Griliches, 1961; Liviatan, 1963). This will yield consistent, albeit inefficient, estimates.⁴⁴ Intuitively, including only the predicted component of lagged currency shares enhances the plausibility that the lag is picking up genuine inertia effects, rather than merely persistent random errors. Another approach is that of Hatanaka (1974), which includes both the fitted value and the residual from the first-stage regression in the second stage and yields estimates that are both consistent and efficient.

Columns 4 and 5 of Table 2 report the results for the two approaches. The estimates are strikingly close to those obtained with the baseline specification, in terms of sign, statistical significance and economic magnitude (at 0.90, the magnitude of the estimated lagged coefficient is somewhat lower using the Griliches-Liviatan approach). Overall, these results are consistent with the idea that we are picking up genuine inertia effects and not merely persistence in the error term.

In Table 3, column 1, we exclude France, the single largest debtor in both US dollar and sterling. In column 2 we control for the fact that the number of countries reporting data varies over time, which could distort our baseline results if large outliers start (or discontinue) reporting data, thereby creating significant breaks in the series. We do this by including as additional control variable the number of countries reporting data on foreign currency debt composition per year. The results again remain largely unaffected.

⁴⁴ Inefficient since the adjustment does not correct for error autocorrelation.

We can also use currency shares calculated at constant exchange rates rather than current rates (the use of current rates being the established practice in the literature), in order to take into account possible valuation effects arising from e.g. devaluations. In this case the estimated impact of financial deepening is somewhat smaller. The effect of persistence remains broadly unchanged, while that of size declines markedly in magnitude and that of credibility again loses its significance (column 3). Importantly, the estimate for financial deepening remains positive, although it is now smaller in magnitude and significant at the 12% level of confidence only.

Next we add a proxy for economic proximity, namely the bilateral share of trade with the US (respectively the UK), to test whether our results are robust to taking into account the intensity of economic relations between debtor economies and those issuing international currencies.⁴⁵ The new variable enters positively and is statistically significant, in line with expected theoretical priors. The other results remain unaltered (credibility effects turn positive, but remain statistically insignificant; see column 4).

As an alternative measure of financial development, we focus on market liquidity as opposed to market size, substituting the short-term dollar-sterling interest differential for bank claims scaled by GDP.⁴⁶ Flandreau and Jobst (2009) argue that in a credible gold standard the short-term interest differential is a very good measure of relative market liquidity. We define US market liquidity as the differential between the US short term interest rate and the corresponding sterling rate (i.e. the lower the spread, the higher the liquidity), and UK market liquidity as the same spread but with an opposite sign. The results (reported in column 5) further support our emphasis on financial development: they confirm that a higher spread is associated with a significant decline in the respective international currency's share. Conversely, they show that greater liquidity is associated with greater use of a particular unit in global debt markets.

We also consider the possible endogeneity of financial development. In Section 5 we provided evidence that financial development, as proxied by the ratio of bank assets to GDP, is an important determinant of the attractions of a currency as a unit of denomination for international bonds. Readers may be worried about reverse causality, that the issuance of bonds in a market may be followed by the deposit, at least temporarily, of the receipts accruing to the issuer in the banks of that same market. Causality, in other words, may run from the value of bond flotations to the level of bank deposits as well as the other way around.

A counter-argument is that our dependent variable is the share of bonds denominated in a particular currency and not the share floated in a particular national market; these are not always the same, as noted above. Another counter-argument is that even if issuers did temporarily deposit the receipts from bond issuance in the banks of the country where the issue was floated, the money to buy the bonds would

⁴⁵ The trade data are taken from Mitchell (1998a, 1998b 1998c). This results in a number of missing observations and a smaller sample size, which is why we limit use of this variable to this section on robustness.

⁴⁶ We take short-term nominal interest rates from Michael Bordo's multi-country dataset on financial crises (<http://sites.google.com/site/michaelbordo/home4>).

have come, in part, from the same place – that is, investors would have withdrawn money from those same banks in order to finance their purchases.

To get at this question, we instrumented bank deposits as a share of GDP using other dimensions of financial development less plausibly affected by bond issuance in the same country: broad money to GDP; private credit to GDP; and narrow money to GDP. The results are in Table 4, column 1.⁴⁷ The second-stage regression (see column 2) yields an estimated coefficient on bank assets which is still positive, significant, and close in magnitude to the baseline (0.3). We also ran a Durbin–Wu–Hausman 2-step simultaneity test and found no evidence of endogeneity between currency share and financial depth.⁴⁸

As a final robustness check, we exclude the five Commonwealth countries from the estimation sample. The results remain strikingly similar to those obtained with the full sample (see Table 5), suggesting that they were not biased by the inclusion of countries heavily oriented to sterling for institutional and political reasons, underscoring the generality of our conclusions.

7. Conclusions and implications

This paper has provided new evidence on the emergence of the US dollar as the leading international currency, focusing on its role as a financing currency in global debt markets.

This evidence challenges the three central tenets of the conventional wisdom on international currencies. First, network externalities, first-mover advantages and inertia matter, but they cannot indefinitely delay the transfer of leadership in the international monetary sphere relative to that in the economic, commercial and financial spheres; they do not dominate to the extent previously thought. Our evidence shows that, abstracting from the Commonwealth countries, the dollar overtook sterling already in 1929, at least 15 years prior to the date cited in other accounts. Even including the Commonwealth countries, which were wedded to sterling for political and institutional reasons, the dollar was already within hailing distance of sterling as a currency of denomination for international bonds by the latter 1920s.

Second, our evidence challenges the presumption that once international monetary leadership is lost, it is gone forever. Although sterling lost its leadership in the 1920s it recovered after 1933 and again ran neck and neck with the dollar at the end of the decade.

⁴⁷ Here we estimate the equation by OLS because we have continuous-uncensored variables on both the left- and right-hand sides of the equation. When we implemented the Griliches-Liviatan and Hatanaka approaches, we used a panel Tobit estimator instead in the first stage (and in the second stage), since we had a (potentially) censored variable on the left hand side. In practice OLS and Tobit estimations gave virtually the same results.

⁴⁸ Specifically, the residual of a first stage regression of financial depth on the exogenous variables and the instruments was statistically insignificant when added as a regressor to our benchmark specification in a second stage regression.

Third, our findings challenge the presumption that there is room for only one dominant international currency due to strong network externalities and economies of scope. International debt markets in the 1920s and the 1930s were characterised by a bipolar currency system, not a unipolar one. This is true even if one takes into account the Commonwealth countries, which were heavily oriented towards sterling for very institutional and political reasons.

Our results point to the development of US financial markets as the main factor that helped the US dollar overcome sterling's incumbency advantage. We find that financial deepening was the most important contributor to the increase in the share of the US dollar in global foreign public debt between 1918 and 1932. In the case of the UK, economic stagnation (declining relative economic size) was the most important factor accounting for sterling's declining share over the period.

Our findings have implications for the future of the international monetary system. They suggest that a shift from a unipolar dollar-based system to a multipolar system is not impossible; that it could occur sooner than often believed; and that financial deepening will be a key determinant of the ability of currencies other than the dollar to strengthen their international currency status. They point to further financial integration in the euro area as important to the evolution of the euro's international profile in the years ahead and to the opening up of domestic financial markets and the capital account, along with further exchange rate reform as of key importance to that of the Chinese yuan.

The international status of a currency will rest on solid foundations, however, only if financial deepening in the issuing country is sustainable, and not if financial innovation and liberalization simply causes a boom that eventually goes bust. The impact of finance on international currency shares in global debt markets worked both ways during the interwar period. In particular, the collapse of the US banking system and subsequent financial retrenchment was the most important factor contributing to the decline in the share of the US dollar in global foreign public debt between 1932 and 1939.

The yen's experience is another cautionary tale. Attempts by the Japanese authorities to develop the international role of their currency suffered from the bursting of Japan's equity and real estate bubbles in the late 1980s and the banking and economic crisis of the 1990s. This underscores that the compass guiding the pace and scope of financial sector reform should always point to the direction of medium-term sustainability. In turn, this highlights the important role that macro-prudential policies and tools will play in shaping the international status of currencies in the new millennium.

Figure 1: Number of countries reporting data

Note: The figure shows for each year between 1914 and 1946 the number of countries reporting data on the currency composition of their foreign public debt, as available from United Nations (1948).

Figure 2: Global foreign public debt

(Currency breakdown in USD million; at current exchange rates)

Notes: Authors' own estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure plots over time the global stock of foreign public debt, in USD million and at current exchange rates, calculated with our full sample of 33 countries, and broken down into selected currencies.

Figure 3: Global foreign public debt in US dollar – Main debtors
(As a % of total; at current exchange rates; in 1929)

Notes: Authors' own estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure shows for 1929 (roughly the mid-point of our sample) the global stock of US dollar-denominated foreign public debt (amounting to USD 6,828 million) broken down by main debtor regions.

Figure 4: Global foreign public debt in sterling – Main debtors
(As a % of total, at current exchange rates; in 1929)

Notes: Authors' estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure shows for 1929 (roughly the mid-point of our sample) the global stock of sterling-denominated foreign public debt (amounting to USD 10,232 million) broken down by main debtor regions.

Figure 5a: Global foreign public debt – Selected currency shares
(As a % of total; at current exchange rates)

Notes: Authors' own estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure shows the evolution over time of the shares of sterling, US dollar, gold and other currencies in the global stock of foreign public debt (in % and at current exchange rates) based on our full sample of 33 countries. Data for Australia, Canada, New Zealand and South Africa refer to the location (London or New York) where debt was “payable”, “redeemable” or “due” and are not strictly comparable with those of the remaining 29 countries whose data refer to actual foreign currency debt denomination.

Figure 5b: Global foreign public debt (excl. Commonwealth countries) – Selected currency shares

(As a % of total; at current exchange rates)

Notes: Authors' own estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure shows the evolution over time of the shares of sterling, US dollar, gold and other currencies in the global stock of foreign public debt (in % and at current exchange rates) based on a restricted sample of 28 countries, i.e. the full sample minus our five Commonwealth countries (India, Australia, Canada, New Zealand and South Africa).

Figure 6: Global foreign public debt – Alternative methods to calculate currency shares
(As a % of total)

a. At constant (end-1930) exchange rates (incl. France)

b. At current exchange rates (excl. France)

c. At current exchange rates, arithmetic average across 33 countries

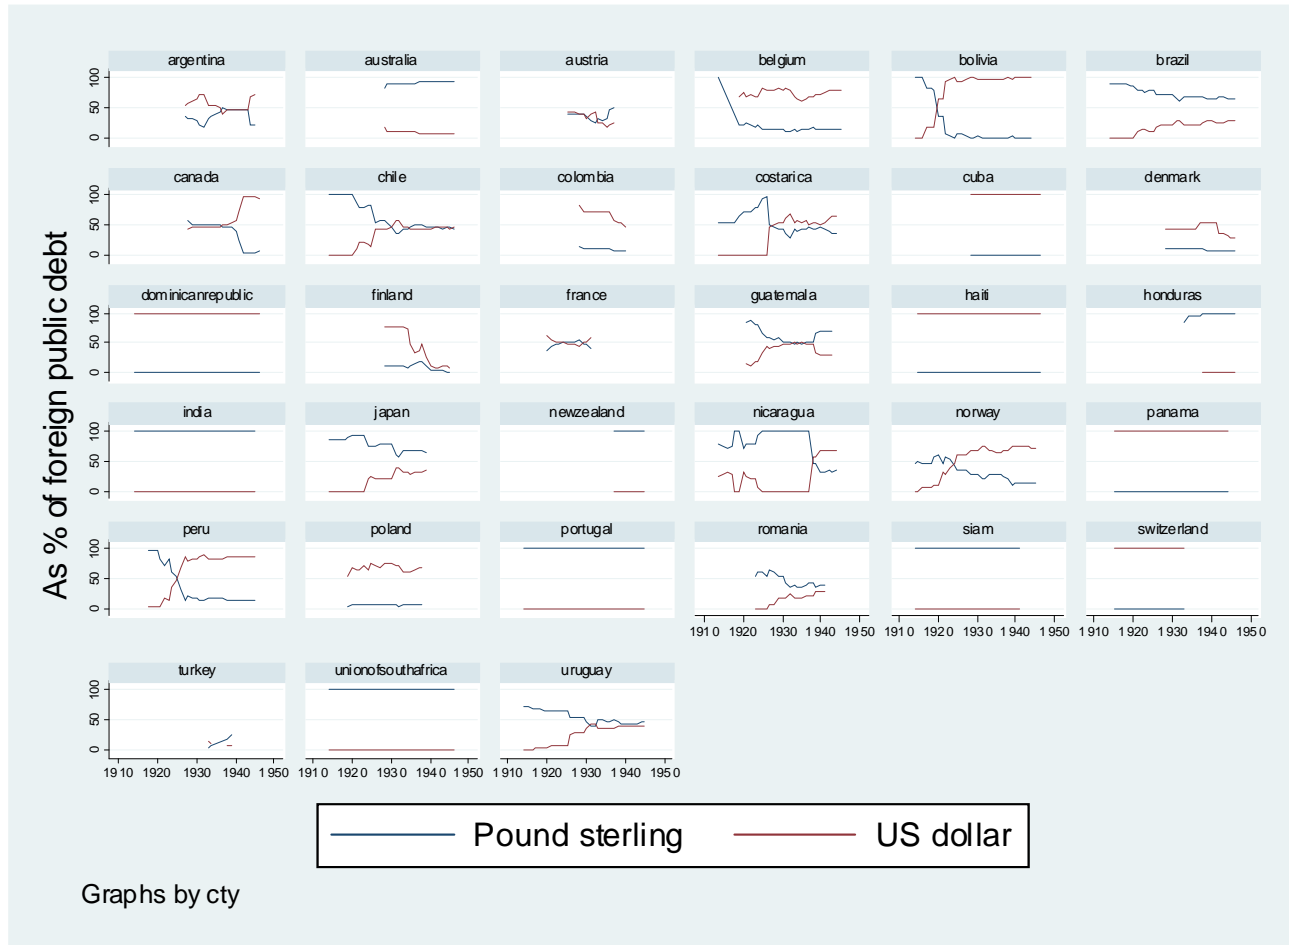

d. At current exchange rates, excluding Commonwealth countries or those issuing only in US dollar or sterling

Notes: Authors' own estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure shows the evolution over time of the shares of sterling, US dollar, gold and other currencies in the global stock of foreign public debt using alternative methods to calculate currency shares and based on our full sample of 33 countries (except Figure 6d). Data for Australia, Canada, New Zealand and South Africa refer to the location (London or New York) where debt was “payable”, “redeemable” or “due” and are not strictly comparable with those of the remaining 29 countries whose data refer to actual foreign currency debt denomination.

Figure 7: Share of US dollar/sterling debt in foreign public debt – Breakdown by country
 (% at current exchange rates)

Notes: Authors’ own estimates based on United Nations (1948) as well as the *GFD* and *Measuring Worth* databases on exchange rates. The figure shows the evolution over time of the shares of the US dollar and sterling in the foreign public debt of each of our sample’s 33 countries (in % and at current exchange rates). Data for Australia, Canada, New Zealand and South Africa refer to the location (London or New York) where debt was “payable”, “redeemable” or “due” and are not strictly comparable with those of the remaining 29 countries whose data refer to actual foreign currency debt denomination.

Figure 8: Estimated contributions to the change in the share of the US dollar in global foreign public debt between 1918 and 1932
(In percentage points)

Figure 9: Estimated contributions to the change in the share of sterling in global foreign public debt between 1918 and 1932
(In percentage points)

Notes: The contributions reported in Figures 8 and 9 are calculated using the estimated parameters of benchmark model (6) of Table 1. They include dynamic effects which we calculate as follows. For each year t between 1919 and 1932 we calculate the contribution of variable z (i.e. either size, credibility or financial deepening) to the change in the average share of the US dollar (sterling) in global foreign public debt y as $(\sum_{i=0, \dots, \infty} \rho^i \theta dz_{t-i})/dy_t$, where θ is the estimated parameter for z , ρ is the estimated parameter for the lag of y , and where $dy_t = y_t - y_{t-1}$. The overall contribution of z to the overall change in y throughout the period is obtained by summing the 14 annual contributions between 1919 and 1932. Recall also that the estimated effect of credibility was found to be statistically insignificant.

Figure 10: Estimated contributions to the change in the share of the US dollar in global foreign public debt between 1932 and 1939
(In percentage points)

Notes: Please refer to the notes to Figures 8 and 9.

Table 1: Baseline model estimates

| | (1) | (2) | (3) | (4) | (5) | (6) |

Uruguay. *Deuda Pública Nacional, Anuario Estadístico*.

Appendix II: Country-level information on the data availability on currency composition of foreign public debt

Argentina. Annual data from 1927 to 1946 (with missing observations for the year 1928 which were filled with interpolation) in six currencies (sterling, US dollar, Spanish peseta, Swiss franc, Italian lira and gold Argentinean peso) are available from United Nations (1948, p. 11). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of -period) market exchange rates. Debt in gold peso converted to US dollar using the exchange rate at which Argentina re-entered the gold standard in 1927 (1.0385 ARS/USD).

Australia. Annual data for 1928 and 1937 to 1947 on bonds “redeemable” in London and in New York are available from United Nations (1948, p. 18). Data are interpolated for the period 1929-1936 by assuming that currency shares remain constant at the average of 1928 and 1937 values. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Austria. Annual data from 1925 to 1937 in 15 currencies (sterling, US dollar, French franc, Swiss franc, Belgian franc, gold franc, Dutch Gulden, Italian lira, Spanish peseta, Swedish crown, Norwegian crown, Danish crown, Czech crown, Egyptian pound and German Reichmark) are available from United Nations (1948, p. 19). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of -period) market exchange rates. Debt in gold franc (issued in 1932) converted to US dollar amounts using the Franc Poincaré 1928 parity (25.575 gold francs per US dollar). Data on debt issued in Czech crown was converted into US dollar amounts using the exchange rate of the koruna vs. the US dollar available from the United Nations volume (Table I, p. 49). Data on debt issued in Egyptian pound not converted to US dollar amounts due to missing exchange rate data (and thereby discarded).

Belgium. Annual data from 1919 to 1945 in seven currencies (sterling, US dollar, French franc, Dutch gulden, Swiss franc, Swedish crown and Canadian dollar) are available from United Nations (1948, p. 22). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of -period) market exchange rates.

Bolivia. Annual data from 1914 to 1944 in two currencies (sterling, US dollar) are available from United Nations (1948, p. 25). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of -period) market exchange rates.

Brazil. Annual data from 1914 to 1946 in four currencies (sterling, US dollar, French franc, gold franc) are available from United Nations (1948, p. 28). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of -period) market exchange rates. Debt in gold franc (issued in 1914) converted to US dollar amounts using the Franc Germinal 1914 parity (5.095 gold francs per US dollar).

Canada. Annual data for 1928 and 1937 to 1947 on bonds “payable” in London and in New York are available from United Nations (1948, p. 37). Data are interpolated for the period 1929-1936 by assuming that currency shares remain constant at the average of 1928 and 1937 values. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Chile. Annual data from 1914 to 1946 in three currencies (sterling, US dollar, Swiss franc) are available from United Nations (1948, p. 38). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

Colombia. Annual security-by-security data for 1928 and 1937 to 1944 on bonds in two currencies (sterling, US dollar) are available from United Nations (1948, p. 44). Due to large bond amounts in unspecified currencies (National City Bank and others’; ‘Export and Import Bank, Washington’; ‘Conversion bonds’) data post-1940 had to be discarded. Data are interpolated for the period 1929-1936 by assuming that currency shares remain constant at the average of 1928 and 1937 values. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Costa Rica. Annual data from 1914 to 1944 in three currencies (sterling, US dollar, French franc) are available from United Nations (1948, p. 45). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

Cuba. Annual data from 1928 to 1946 in one currency (US dollar) are available from United Nations (1948, p. 48), reported in millions of national currency. Foreign debt consists of US dollar obligations. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Denmark. Annual security-by-security data for 1928 and 1935 to 1944 on bonds in five currencies (sterling, US dollar, Dutch gulden, Swedish kronor and Swiss franc and some issues in multiple currencies) are available from United Nations (1948, pp. 53-54). Data are interpolated for the period 1929-1934 by assuming that currency shares remain constant at the average of 1928 and 1935 values. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Dominican Republic: Annual data for 1914-1946 on bonds in one currency (US dollar) are available from United Nations (1948, p. 55).

Finland. Annual security-by-security data for 1928 and 1934 to 1945 on bonds in three currencies (sterling, US dollar, Swedish kronor and some issues in unspecified currencies) are available from United Nations (1948, pp. 63). Data are interpolated for the period 1929-1933 by assuming that currency shares remain constant at the average of 1928 and 1934 values. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

France. Annual data from 1920 to 1931 in two currencies (sterling, US dollar) are available from United Nations (1948, p. 65) corresponding to the debt owed to the “allied governments”. Data on commercial (private) debt (denominated in gold franc) are also available accounting for approximately 15% of total foreign debt. Since we focus on public debt in the paper, we exclude such commercial debt from our empirical analysis. Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of -period) market exchange rates.

Guatemala. Annual data for 1915 and from 1921 to 1946 in two currencies (sterling, US dollar) are available from United Nations (1948, p. 74). With the exception of a 4% sterling loan, the whole of foreign debt consists of US dollar obligations.

Haiti. Annual data from 1915 to 1946 in one currency (US dollar) are available from United Nations (1948, p. 76-77). Foreign debt consists of two issues of dollar bonds. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Honduras. Annual data for 1933 and from 1938 to 1946 in one currency (sterling) are available from United Nations (1948, p. 78-79). Foreign debt consists of four loans in sterling. Data are interpolated for the period 1934-1937 by assuming that currency shares remain constant at the average of 1933 and 1938 values. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

India. Annual data from 1914 to 1945 in one currency (sterling) are available from United Nations (1948, p. 83). Foreign debt consists entirely of sterling obligations. Book value of outstanding debt amounts converted to US dollar amounts using (end-of-period) market exchange rates.

Japan. Annual data from 1914 to 1939 in three currencies (sterling, US dollar, French franc) are available from United Nations (1948, p. 93). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

Nicaragua. Annual data from 1914 to 1944 in two currencies (sterling, US dollar) are available from United Nations (1948, pp. 104-105). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

New Zealand. Annual data from 1937 to 1945 on bonds “due” in London and in Australia are available from United Nations (1948, pp. 100-103). Annual data from 1917 to 1938 on debt “domiciled” in London and Australia are taken from the New Zealand Official Year-Book. Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Norway. Annual data from 1914 to 1945 in five currencies (sterling, US dollar, French franc, Swedish crown and Swiss franc) are available from United Nations

(1948, p. 107). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

Panama. Annual data from 1915 to 1944 in one currency (dollar) are available from United Nations (1948, p. 110). Foreign debt consists entirely of dollar obligations. Data interpolated for the years 1917 and for 1923.

Peru. Annual data from 1918 to 1945 in three currencies (sterling, US dollar, French franc) are available from United Nations (1948, p. 114). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

Poland. Annual data from 1919 to 1939 in 13 currencies (sterling, US dollar, gold francs, Austrian gold crowns, Austrian gold florins, Austrian schillings, French franc, Italian Lira, Dutch florin, Norwegian kroner, Swedish kroner, Danish kroner and Swiss francs) are available from United Nations (1948, p. 117). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates. The gold debt data includes only debt in gold franc. Data on debt issued in Austrian gold crown and Austrian gold florin not converted to US dollar amounts due to missing exchange rate data and thereby discarded.

Portugal. Annual data from 1914 to 1946 in one currency (sterling) are available from United Nations (1948, pp. 120-121). Foreign debt entirely consists of sterling obligations. Book value of outstanding debt amounts converted to US dollar amounts using (end-of-period) market exchange rates.

Romania. Annual data from 1923 to 1942 in 14 currencies (sterling, US dollar, gold franc, gold lei, gold florin, gold crown, French franc, Swiss franc, Italian lira, Belgian franc, German Reichmark, Scandinavian crown, Czechoslovak crown and paper crown) are available from United Nations (1948, pp. 124-125). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates. Debt in gold franc (issued in 1923) converted to US dollar using the Franc Germinal 1914 parity (5.095 gold francs per US dollar). Data on debt issued in gold lei, gold florin, gold crown, Scandinavian crown and paper crown not converted to US dollar amounts due to missing exchange rate data and thereby discarded. In order to avoid a gap in the data series due to the change in the financial year from 31 December to March from 1931 onwards, we have assigned the data covering the period 1 January 1930-31 March 1932 to the year 1931.

Siam. Annual data from 1914 to 1941 in one currency (sterling) are available from United Nations (1948, p. 129). Foreign debt consists entirely of sterling obligations. Book value of outstanding debt amounts converted to US dollar amounts using (end-of-period) market exchange rates.

South Africa (Union of). Annual data for 1914 to 1947 on bonds “payable” in London are available from United Nations (1948, pp. 143-145). Book value of outstanding debt amounts reported in local currency converted to US dollar amounts using (end-of-period) market exchange rates.

Switzerland. Annual data from 1915 to 1933 in one currency (US dollar) are available from United Nations (1948, p. 1938). Foreign debt entirely consists of US dollar obligations.

Turkey. Annual data from 1933 to 1934 and from 1937 to 1938 in eight currencies (sterling, gold sterling, US dollar, gold dollar, French franc, German Reichmark, Swedish crown and Turkish lira) are available from United Nations (1948, p. 141). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates.

Uruguay. Annual data from 1914 to 1946 in four currencies (sterling, US dollar, gold franc and gold peso) are available from United Nations (1948, pp. 154-155). Book value of outstanding debt amounts in these currencies converted to US dollar amounts using (end-of-period) market exchange rates. Debt in gold franc (issued in or before 1914 converted to US dollar using the Franc Germinal 1914 parity (5.095 gold francs per US dollar). Debt in gold peso (issued in 1919) is converted to US dollar amounts using the exchange rate in 1919 (1.3698 ARS/USD).

Appendix III: Outstanding amounts of international debt securities
Selected currency shares
(As a % of total)

Notes: BIS, ECB and authors' calculations. International debt securities (bonds and notes and money market instruments) according to the so-called "narrow" definition (i.e. excluding home currency issuance (see ECB (various issues) as well as Detken and Hartmann (2000) and (2002)). The share of the euro prior to 1999 is the sum of the share of the euro legacy currencies, net of intra-euro area issuance. Both public and private debt is included here. Data are unavailable prior to 1999 for sterling.
