ABSTRACT

First, we propose a more efficient implementation of the Smolyak method for interpolation, namely, we show how to avoid costly evaluations of repeated basis functions in the conventional Smolyak formula. Second, we extend the Smolyak method to include anisotropic constructions; this allows us to target higher quality of approximation in some dimensions than in others. Third, we show how to effectively adapt the Smolyak hypercube to a solution domain of a given economic model. Finally, we advocate the use of low-cost fixed-point iteration, instead of conventional time iteration. In the context of one- and multi-agent growth models, we find that the proposed techniques lead to substantial increases in accuracy and speed of a Smolyak-based projection method for solving dynamic economic models.

1 Introduction

In a seminal paper, a Russian mathematician Sergey Smolyak (1963) proposes a sparse-grid method that allows to efficiently represent, integrate and interpolate functions on multidimensional hypercubes. The Smolyak method is not subject to the curse of dimensionality and can be used to solve large-scale applications. A pioneering work of Krueger and Kubler (2004) introduces the Smolyak method to economics in the context of a projection-style iterative method for solving multi-period overlapping generation models. The Smolyak methods are also used to solve portfolio-choice problems (Gavilan-Gonzalez and Rojas (2009)); to develop state-space filters tractable in large-scale problems (Winschel and Krätzig (2010)); to solve models with infinitely lived heterogenous agents (Malin et al. (2011), Gordon (2011), Brumm and Scheidegger (2013)); and to solve new Keynesian models (Fernández-Villaverde et al. (2012)).

While the Smolyak method enables us to study far larger problems than do tensor-product methods, its computational expense still grows rapidly with the dimensionality of the problem. In particular, Krueger and Kubler (2004) and Malin et al. (2011) document a high computational cost of their solution methods when the number of state variables exceeds twenty. In the paper, we show a more efficient implementation of the Smolyak method that reduces its computational expense, and we propose extensions of the Smolyak method that enable us to more effectively solve dynamic economic models.

First, the conventional Smolyak formula is inefficient. To interpolate a function in a given point, it first causes the computer to create and evaluate a long list of repeated basis functions, and it then constructs linear combinations of such functions to get rid off repetitions. In high-dimensional problems, the number of repetitions is large and slows down computations dramatically. We offer a way to avoid costly evaluations of the repeated basis functions: Instead of conventional nested-set generators, we introduce disjoint-set generators. Nested sets include one another, and as a result, their tensor products contain repeated elements but our disjoint sets do not. This is why our implementation of the Smolyak formula does not have repetitions.[1]

An efficient implementation of the Smolyak method is especially important in the context of numerical methods for solving dynamic economic models which require us to interpolate decision and value functions a very large number of times, e.g., in each grid point, integration node or time period. We save on cost every time when we perform an evaluation of the Smolyak interpolant.

To compute the interpolation coefficients, we use a universal Lagrange interpolation technique instead of the conventional closed-form expressions. Namely, we proceed in three steps: (i) construct M Smolyak grid points; (ii) construct M corresponding Smolyak basis functions; and (iii) interpolate the values of the true function at the grid points using the basis functions. We then solve a system of M linear equations with M unknowns. The cost of solving this system can be high but it is a fixed cost in the context of iterative methods for solving dynamic economic models. Namely, we argue that an expensive inverse in the Lagrange inverse problem can be precomputed up-front (as it does not change along iterations). Furthermore, to ensure numerical stability of a solution to the Lagrange inverse problem, we use families of orthogonal basis functions, such as a Chebyshev family.

---

[1]Our exposition was informed by our personal communication with Sergey Smolyak.

Second, the conventional Smolyak formula is symmetric in a sense that it has the same number of grid points and basis functions for all variables. To increase the quality of approximation, one must equally increase the number of grid points and basis functions for all variables, which may be costly or even infeasible in large-scale applications. In the paper, we present an anisotropic version of the Smolyak method that allows for asymmetric treatments of variables, namely, it enables us to separately choose the accuracy level for each dimension to increase the quality of approximation. In economic applications, variables do not enter symmetrically: decisions or value functions may have more curvature in some variables than in others; some variables may have larger ranges of values than others; and finally, some variables may be more important than the others. For example, in heterogeneous-agent economies, an agent's decision functions may depend more on her own capital stock than on the capital stocks of other agents (e.g., Kollmann et al. (2011)); or we may need more grid points for accurate approximation of endogenous than exogenous state variables (e.g., models based on Tauchen and Hussy's (1991) approximation of shocks). An anisotropic version of the Smolyak method allows us to take into account a specific structure of decision or value functions to solve the economic models more efficiently.

Third, the Smolyak method constructs grid points within a normalized multidimensional hypercube. In economic applications, we must in addition specify how the model's state variables are mapped into the Smolyak hypercube. The way in which this mapping is constructed can dramatically affect the effective size of a solution domain, and hence, the quality of approximation. In the paper, we show how to effectively adapt the Smolyak grid to a solution domain of a given economic model. We specifically construct a parallelotope that encloses a high-probability area of the state space of the given model, and we reduce the size of the parallelotope to minimum by reorienting it with a principle-component transformation of state variables. Judd et al. (2011) find that solution methods focusing on a relevant domain yield a better fit inside such a domain than methods focusing on larger domains and facing a trade off between the fit inside and outside the relevant domain. For the same reason, an adaptive domain increase the accuracy of the Smolyak method.

Finally, the Smolyak method for interpolation is just one ingredient of a numerical method for solving dynamic economic models. In particular, Krueger and Kubler (2004) and Malin et al. (2011) complemented Smolyak interpolation with other computational techniques that are tractable in large-scale problems, such as Chebyshev polynomials, monomial integration and learning-style procedure for finding polynomial coefficients. Nonetheless, there is one technique – time iteration – that is expensive in their version of their numerical procedure. Time iteration is traditionally used in dynamic programming: given functional forms for future value function, it solves for current value function using a numerical solver. In works similarly in the context of the Euler equation methods: given functional forms for future decision functions, it solves for current decision functions using a numerical solver. However, there is a simple derivative-free alternative to time iteration - fixed point iteration - that can solve large systems of equtions rapidly using only straightforward calculations. In the present paper, we replace time iteration used in the existing version of the Smolyak method with fixed-point iteration, avoiding thus the need of a numerical solver.

We assess the performance of the Smolyak-based projection method in the context of one-

and multi-agent neoclassical stochastic growth models with up to 20 state variables. Our analysis shows that there are substantial accuracy gains from using anisotropic grid and adaptive domain even in the simplest case with two state variables: the maximum residuals in the Euler equations can be reduced by 5-10 times compared to those produced by the baseline isotropic Smolyak method with the standard hypercube domain (holding the number of the coefficients roughly the same). In multidimensional problems – the real interest of our analysis – the accuracy gains from using an anisotropic grid and adaptive domain reach two orders of magnitude in some examples. Our cost grows fairly slowly with the dimensionality of the problem. In particular, our MATLAB code delivers a second-level Smolyak approximation to a model with ten countries (twenty state variables) in about 45 minutes. For comparison, the Fortran code of Malin et al. (2011), based on the conventional Smolyak method, solves a similar model in about 10 hours. Moreover, we are able to produce a very accurate third-level polynomial approximation to a ten-country model although such an approximation is computationally demanding even for our efficient implementation of the Smolyak method (our running time increases to nearly 45 hours).

The rest of the paper is organized as follows: In Section 2, we illustrate the inefficiency of the conventional Smolyak formula. In Section 3, we introduce an alternative implementation of the Smolyak method based on disjoint-set unidimensional generators and Lagrange interpolation. In Sections 4.2 and 5, we develop versions of the Smolyak method with anisotropic grid and adaptive domain, respectively. In Section 6, we assess the performance of the Smolyak-based projection method in the context of one- and multi-agent growth models. Finally, in Section 7, we conclude.

2   Conventional Smolyak method for interpolation

In this section, we describe the conventional Smolyak method for interpolation. In Section 2.1, we outline the idea of the Smolyak method and review the related literature. In Sections 2.2, 2.3 and 2.4, we show how to construct the Smolyak grid points, Smolyak polynomial and Smolyak interpolating coefficients, respectively. Finally, in Section 2.5, we argue that the conventional Smolyak method is inefficient.

2.1   Smolyak method at glance

The problem of representing and interpolating multidimensional functions commonly arises in economics. In particular, when solving dynamic economic models, one needs to represent and interpolate decision functions and value functions in terms of state variables. With few state variables, one can use tensor-product rules but such rules become intractable when the number of state variables increases. For example, if we have five grid points for one variables, a tensor product grid for d variables has 5^d grid points, which is a large number even for moderately large d. Bellman (1961) referred to the exponential growth in complexity as a curse of dimensionality.

In a seminal work, Smolyak (1963) introduces a numerical technique for representing multidimensional functions, which is tractable in problems with high dimensionality. The key idea of the Smolyak's (1963) analysis is that some elements produced by tensor-product rules are more

important for representing multidimensional functions than the others. The Smolyak method orders all elements produced by a tensor-product rule by their potential importance for the quality of approximation and selects a relatively small number of the most important elements. A parameter, called a *level of approximation,* controls how many tensor-product elements are included into the Smolyak grid. By increasing the level of approximation, one can add new elements and improve the quality of approximation.[2]

Examples of Smolyak grids under approximation levels $\mu = 0,\ 1,\ 2,\ 3$ are illustrated in Figure 1 for the two-dimensional case. For comparison, we also show a tensor-product grid of 5^2 points.

Figure 1: Smolyak grids versus a tensor-product grid
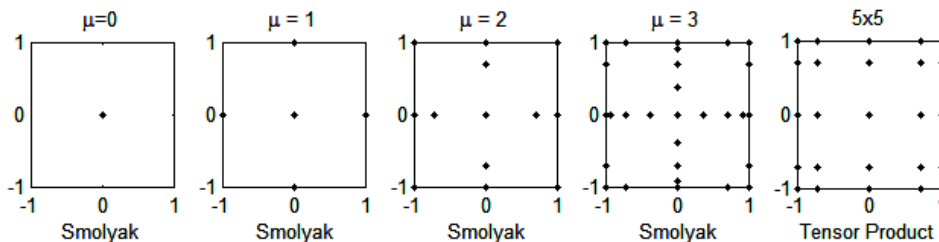

In Table 1, we compare the number of points in the Smolyak grid and that in the tensor-product grid with five grid points in each dimension. The number of points in a Smolyak grid

Table 1: Number of grid points: tensor-product grid with 5 points in each dimension versus Smolyak grids

d	Tensor-product grid with 5^d points	Smolyak grid		
		$\mu = 1$	$\mu = 2$	$\mu = 3$
1	5	3	5	9
2	25	5	13	29
10	9,765,625	21	221	1581
20	95,367,431,640,625	41	841	11561

grows polynomially with the dimensionality d, meaning that the Smolyak method is not subject to the curse of dimensionality. In particular, for $\mu = 1$ and $\mu = 2$, the number of the Smolyak grid points grows as $1 + 2d$ and $1 + 4d + 4d\,(d-1)$, i.e., linearly and quadratically, respectively. A relatively small number of points in Smolyak grids contrasts sharply with a huge number of points in tensor-product grids in a high-dimensional case. Because of this, Smolyak grids are also called sparse grids.

---

[2]The level of approximation plays the same role in the Smolyak construction as the order of expansion in the Taylor series, i.e., we include the terms up to a given order, and we neglect the remaining high-order terms.

To interpolate multidimensional functions off the Smolyak grid, two broad classes of interpolants are used in mathematical literature. One class includes piecewise local basis functions; see, e.g., Griebel (1998) and Bungartz and Griebel (2004) for related mathematical results, and see Brumm and Scheidegger (2013) for an economic application. Piecewise functions are very flexible and make it possible to vary the quality of approximations over different areas of the state space as needed. However, the resulting approximations are non-smooth and non-differentiable and also, they have a high computational expense (this interpolation technique is still subject to the curse of dimensionality).

The other class of Smolyak interpolants includes global polynomial functions; see, e.g., Delvos (1982), Wasilkowski and Woźniakowski (1999) and Barthelmann et al. (2000) for a mathematical background. Global polynomial approximations are smooth and continuously differentiable and also, they are relatively inexpensive. However, their flexibility and adaptivity are limited. In economics, global polynomial approximation are used in Krueger and Kubler (2004), Gavilan-Gonzalez and Rojas (2009), Winschel and Krätzig (2010), Gordon (2011), Malin et al. (2011) and Fernández-Villaverde et al. (2012). In the present paper, we also confine our attention to global polynomial approximations. Below, we show the conventional Smolyak method for interpolation in line with Malin et al. (2011).

2.2 Construction of Smolyak grids using unidimensional nested sets

To construct a Smolyak grid, we generate unidimensional sets of grid points, construct tensor products of unidimensional sets and select a subsets of grid points satisfying the Smolyak rule.

2.2.1 Unidimensional nested sets of points

The Smolyak construction begins with one dimension. To generate unidimensional grid points, we use extrema of Chebyshev polynomials (also known as Chebyshev-Gauss-Lobatto points or Clenshaw-Curtis points); see Appendix A. We do not use all consecutive extrema but those that form a sequence $S_1, S_2, ...$ satisfying two conditions:

Condition 1. A set S_i, $i = 1, 2, ...$, has $m(i) = 2^{i-1} + 1$ points for $i \geq 2$ and $m(1) \equiv 1$.

Condition 2. Each subsequent set contains all points of the previous set, $S_i \subset S_{i+1}$. Such sets are called *nested*.[3]

Below, we show the first four nested sets composed of extrema of Chebyshev polynomials:

$i = 1 : S_1 = \{0\}$;
$i = 2 : S_2 = \{-1, 0, 1\}$;
$i = 3 : S_3 = \left\{-1, \frac{-1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}}, 1\right\}$;
$i = 4 : S_4 = \left\{-1, \frac{-\sqrt{2+\sqrt{2}}}{2}, \frac{-1}{\sqrt{2}}, \frac{-\sqrt{2-\sqrt{2}}}{2}, 0, \frac{\sqrt{2-\sqrt{2}}}{2}, \frac{1}{\sqrt{2}}, \frac{\sqrt{2+\sqrt{2}}}{2}, 1\right\}$.

---

[3]There are many other ways to construct sets of points that have a nested structure. For example, we can use subsets of equidistant points; see Appendix A for a discussion. Gauss-Patterson points also lead to nested sets, however, the number of points in such sets is different, namely, $m(i) = 2^{i-1} - 1$; see Patterson (1968), etc.

2.2.2 Tensor products of unidimensional nested sets of points

Next, we construct tensor products of unidimensional sets of points. As an illustration, we consider a two-dimensional case with $i = 1, 2, 3$ in each dimension.

Table 2: Tensor products of disjoint sets of unidimensional grid points for the two-dimensional case

	$S_{i_1} \backslash S_{i_2}$	$i_2 = 1$ 0	$i_2 = 2$ $-1, 0, 1$	$i_2 = 3$ $-1, \frac{-1}{\sqrt{2}}, 0, \frac{1}{\sqrt{2}}, 1$
$i_1 = 1$	0	$(0,0)$	$(0,-1),(0,0),(0,1)$	$(0,-1),(0,\frac{-1}{\sqrt{2}}),(0,0),(0,\frac{1}{\sqrt{2}}),(0,1)$
$i_1 = 2$	-1 0 1	$(-1,0)$ $(0,0)$ $(1,0)$	$(-1,-1),(-1,0),(-1,1)$ $(0,-1),(0,0),(0,1)$ $(1,-1),(1,0,),(1,1)$	$(-1,-1),(-1,\frac{-1}{\sqrt{2}}),(-1,0),(-1,\frac{1}{\sqrt{2}}),(-1,1)$ $(0,-1),(0,\frac{-1}{\sqrt{2}}),(0,0),(0,\frac{1}{\sqrt{2}}),(0,1)$ $(1,-1),(1,\frac{-1}{\sqrt{2}}),(1,0),\left(1,\frac{1}{\sqrt{2}}\right)(1,1)$
$i_1 = 3$	-1 $\frac{-1}{\sqrt{2}}$ 0 $\frac{1}{\sqrt{2}}$ 1	$(-1,0)$ $(\frac{-1}{\sqrt{2}},0)$ $(0,0)$ $(\frac{1}{\sqrt{2}},0)$ $(1,0)$	$(-1,-1),(-1,0),(-1,1)$ $(\frac{-1}{\sqrt{2}},-1),(\frac{-1}{\sqrt{2}},0),(\frac{-1}{\sqrt{2}},1)$ $(0,-1),(0,0),(0,1)$ $(\frac{1}{\sqrt{2}},-1),(\frac{1}{\sqrt{2}},0),(\frac{1}{\sqrt{2}},1)$ $(1,-1),(1,0),(1,1)$	$(-1,-1),(-1,\frac{-1}{\sqrt{2}}),(-1,0),(-1,\frac{1}{\sqrt{2}}),(-1,1)$ $(\frac{-1}{\sqrt{2}},-1),(\frac{-1}{\sqrt{2}},\frac{-1}{\sqrt{2}}),(\frac{-1}{\sqrt{2}},0),(\frac{-1}{\sqrt{2}},\frac{1}{\sqrt{2}}),(\frac{-1}{\sqrt{2}},1)$ $(0,-1),(0,\frac{-1}{\sqrt{2}}),(0,0),(0,\frac{1}{\sqrt{2}}),(0,1)$ $(\frac{1}{\sqrt{2}},-1),(\frac{1}{\sqrt{2}},\frac{-1}{\sqrt{2}}),(\frac{1}{\sqrt{2}},0),(\frac{1}{\sqrt{2}},\frac{-1}{\sqrt{2}}),(\frac{1}{\sqrt{2}},1)$ $(1,-1),(1,\frac{-1}{\sqrt{2}}),(1,0),\left(1,\frac{1}{\sqrt{2}}\right)(1,1)$

In Table 2, i_1 and i_2 are indices that correspond to dimensions one and two respectively; a column S_{i_1} and a row S_{i_2} (see $S_{i_1} \backslash S_{i_2}$) show the sets of unidimensional elements that correspond to dimensions one and two, respectively; (ζ_ℓ, ζ_n) denotes a two-dimensional grid point obtained by combining a grid point ζ_ℓ in dimension 1 and a grid point ζ_n in dimension two.

2.2.3 Smolyak sparse grids

Smolyak (1963) offers a rule that tells us which tensor products must be selected from the table. For the two-dimensional case, we must select tensor products (cells of Table 2) for which the following condition is satisfied:

$$d \le i_1 + i_2 \le d + \mu, \tag{1}$$

where $\mu \in \{0, 1, 2, ...\}$ is the approximation level, and d is the dimensionality (in our case, $d = 2$). In other words, the sum of a column i_1 and a raw i_2, must be between d and $d + \mu$.

Let $\mathcal{H}^{d,\mu}$ denote a Smolyak grid for a problem with dimensionality d and approximation level μ. Let us construct Smolyak grids for $\mu = 0$, 1, 2 and $d = 2$ using the Smolyak rule (1).

- If $\mu = 0$, then $2 \le i_1 + i_2 \le 2$. The only cell that satisfies this restriction is $i_1 = 1$ and $i_2 = 1$, so that the Smolyak grid has just one grid point,

$$\mathcal{H}^{2,0} = \{(0,0)\} . \tag{2}$$

- If $\mu = 1$, then $2 \leq i_1 + i_2 \leq 3$. The three cells that satisfy this restriction are (a) $i_1 = 1$, $i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$, and the corresponding five Smolyak grid points are

$$\mathcal{H}^{2,1} = \{(0,0), (-1,0), (1,0), (0,-1), (0,1)\}. \tag{3}$$

- If $\mu = 2$, then $2 \leq i_1 + i_2 \leq 4$. There are six cells that satisfy this restriction: (a) $i_1 = 1$, $i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$; (d) $i_1 = 1$, $i_2 = 3$; (e) $i_1 = 2$, $i_2 = 2$; (f) $i_1 = 3$, $i_2 = 1$, and there are thirteen Smolyak grid points,

$$\mathcal{H}^{2,2} = \{(-1,1), (0,1), (1,1), (-1,0), (0,0), (1,0), (-1,-1), (0,-1),$$
$$(1,-1), (\frac{-1}{\sqrt{2}},0), (\frac{1}{\sqrt{2}},0), (0,\frac{-1}{\sqrt{2}}), (0,\frac{1}{\sqrt{2}})\}. \tag{4}$$

Smolyak grids $\mathcal{H}^{2,0}$, $\mathcal{H}^{2,1}$ and $\mathcal{H}^{2,2}$ are those that are shown in the first three subplots of Figure 1.

2.3 Smolyak formula for interpolation using unidimensional nested sets

The conventional technique for constructing a Smolyak polynomial function also builds on unidimensional nested sets and mimics the construction of a Smolyak grid.

2.3.1 Smolyak polynomial

Let $\widehat{f}^{d,\mu}$ denote a Smolyak polynomial function (interpolant) in dimension d, with approximation level μ. The Smolyak interpolant is a linear combination of tensor-product operators $p^{|i|}$ whose indices $|i|$ satisfy a constraint $|i| \equiv i_1 + ... + i_d$ and is given by

$$\widehat{f}^{d,\mu}(x_1, ..., x_d; b) = \sum_{\max(d,\mu+1) \leq |i| \leq d+\mu} (-1)^{d+\mu-|i|} \binom{d-1}{d+\mu-|i|} p^{|i|}(x_1, ..., x_d), \tag{5}$$

where $(-1)^{d+\mu-|i|} \binom{d-1}{d+\mu-|i|}$ is a counting coefficient. For each $|i|$ satisfying $\max(d, \mu+1) \leq |i| \leq d + \mu$, a tensor-product operator $p^{|i|}(x_1, ..., x_d)$ is defined as

$$p^{|i|}(x_1, ..., x_d) = \sum_{i_1 + ... + i_d = |i|} p^{i_1, ..., i_d}(x_1, ..., x_d), \tag{6}$$

and $p^{i_1, ..., i_d} is$ is defined as

$$p^{i_1, ..., i_d}(x_1, ..., x_d) = \sum_{\ell_1=1}^{m(i_1)} ... \sum_{\ell_d=1}^{m(i_d)} b_{\ell_1 ... \ell_d} \psi_{\ell_1}(x_1) \cdots \psi_{\ell_d}(x_d), \tag{7}$$

where $m(i_j)$ is the number of basis functions in dimension j, with $m(i_j) \equiv 2^{i_j-1} + 1$ for $i_j \geq 2$ and $m(1) \equiv 1$; $\psi_{\ell_j}(x_j)$ is a ℓ_jth unidimensional basis function in dimension j with $\ell_j = 1, ..., m(i_j)$; $\psi_{\ell_1}(x_1) \cdots \psi_{\ell_d}(x_d)$ is a d-dimensional basis function and $b_{\ell_1 ... \ell_d}$ are the corresponding polynomial coefficients.

8

2.3.2   Example of Smolyak polynomial under $d = 2$ and $\mu = 1$

We now illustrate the construction of Smolyak polynomial function (5) under $d = 2$ and $\mu = 1$; in Appendix B, we show the construction of such a function under $d = 2$ and $\mu = 2$.

For the case of $\mu = 1$, we have that $2 \leq |i| \leq 3$. This is satisfied in three cases: (a) $i_1 = i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$. From (7), we obtain

$$\text{(a) } p^{1,1} = \sum_{\ell_1=1}^{m(1)}\sum_{\ell_2=1}^{m(1)} b_{\ell_1\ell_2}\psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{11}, \tag{8}$$

$$\text{(b) } p^{1,2} = \sum_{\ell_1=1}^{m(1)}\sum_{\ell_2=1}^{m(2)} b_{\ell_1\ell_2}\psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{11} + b_{12}\psi_2(y) + b_{13}\psi_3(y), \tag{9}$$

$$\text{(c) } p^{2,1} = \sum_{\ell_1=1}^{m(2)}\sum_{\ell_2=1}^{m(1)} b_{\ell_1\ell_2}\psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x), \tag{10}$$

where we assume that $\psi_1(x) = \psi_1(y) \equiv 1$. Collecting the elements p^{i_1,i_2} with the same sum $i_1 + i_2 \equiv |i|$, we obtain

$$p^{|2|} \equiv p^{1,1}, \tag{11}$$

$$p^{|3|} \equiv p^{2,1} + p^{1,2}. \tag{12}$$

Smolyak polynomial function (5) for the case of $d = 2$ and $\mu = 1$ is given by

$$
\begin{aligned}
\widehat{f}^{2,1}(x, y; b) &= \sum_{\max(d,\mu+1)\leq|i|\leq d+\mu} (-1)^{d+\mu-|i|} \binom{d-1}{d+\mu-|i|} p^{|i|} \\
&= \sum_{2\leq|i|\leq3} (-1)^{3-|i|} \binom{1}{3-|i|} p^{|i|} = \sum_{2\leq|i|\leq3} (-1)^{3-|i|} \frac{1}{(3-|i|)!} p^{|i|} \\
&= (-1) \cdot p^{|2|} + 1 \cdot p^{|3|} \\
&= (-1) \cdot p^{1,1} + 1 \cdot (p^{2,1} + p^{1,2}) \\
&= -b_{11} + b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x) + b_{11} + b_{12}\psi_2(y) + b_{13}\psi_3(y) \\
&= b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x) + b_{12}\psi_2(y) + b_{13}\psi_3(y). \quad (13)
\end{aligned}
$$

By construction, the number of basis functions in Smolyak polynomial $\widehat{f}^{2,1}(x, y; b)$ is equal to the number of points in Smolyak grid $\mathcal{H}^{2,1}$. The same is true for a Smolyak grid $\mathcal{H}^{d,\mu}$ and Smolyak polynomial $\widehat{f}^{d,\mu}$ under any $d \geq 1$ and $\mu \geq 0$.

2.4   Smolyak interpolation coefficients

Polynomial coefficients $b_{\ell_1...\ell_d}$'s in (5) must be constructed so that Smolyak polynomial $\widehat{f}^{d,\mu}$ matches the true function f in all points of Smolyak grid $\mathcal{H}^{d,\mu}$.

2.4.1 Closed-form expression for Smolyak interpolation coefficients

There is a closed-form formula for the polynomial coefficients in (5) if multidimensional Smolyak grid points and basis functions are constructed using unidimensional Chebyshev polynomials and their extrema, respectively; see Quarteroni et al. (2000) for a derivation of such formulas. Consider a grid that has $m(i_1), ..., m(i_d)$ grid points and basis functions in dimensions $1, ..., d$, respectively. Then, the corresponding coefficients are given by

$$b_{\ell_1...\ell_d} = \frac{2^d}{(m(i_1) - 1) \cdots (m(i_d) - 1)} \cdot \frac{1}{c_{\ell_1} \cdots c_{\ell_d}}$$
$$\times \sum_{j_1=1}^{m(i_1)} \cdots \sum_{j_d=1}^{m(i_d)} \frac{\psi_{\ell_1}(\zeta_{j_1}) \cdots \psi_{\ell_d}(\zeta_{j_d}) \cdot f(\zeta_{j_1}, ..., \zeta_{j_d})}{c_{j_1} \cdots c_{j_d}}, \quad (14)$$

where $\zeta_{j_1}, ..., \zeta_{j_d}$ are grid points in dimensions $j_1, ..., j_d$, respectively; $c_j = 2$ for $j = 1$ and $j = m(i_d)$; $c_j = 1$ for $j = 2, ..., m(i_d) - 1$. If along any dimension d, we have $m(i_d) = 1$, this dimension is dropped from computation, i.e., $m(i_d) - 1$ is set to 1 and $c_{j_d} = c_1$ is set to 1.

2.4.2 Example of the Smolyak coefficients under $d = 2$ and $\mu = 1$

We must compute the coefficients $\{b_{11}, b_{21}, b_{31}, b_{12}, b_{13}\}$ so that polynomial function $\widehat{f}^{2,1}$, given by (13), matches true function f on Smolyak grid $\mathcal{H}^{2,1}$ given by (3). For $\mu = 1$, the set of Chebyshev polynomial basis are $\{\psi_1(x), \psi_2(x), \psi_3(x)\} = \{1, x, 2x^2 - 1\}$ (and we have the same polynomial basis for y, namely, $\{1, y, 2y^2 - 1\}$) and the extrema of Chebyshev polynomials are $\{\zeta_1, \zeta_2, \zeta_3\} = \{0, -1, 1\}$.

For b_{21}, formula (14) implies

$$\begin{aligned}
b_{21} &= \frac{2^2}{3-1} \cdot \frac{1}{c_2 \cdot c_1} \sum_{j_1=1}^{3} \frac{\psi_2(\zeta_{j_1}) \cdot \psi_1(\zeta_1) \cdot f(\zeta_{j_1}, \zeta_1)}{c_{j_1} \cdot 1} \\
&= \frac{\psi_2(\zeta_1) \cdot f(\zeta_1, \zeta_1)}{c_1} + \frac{\psi_2(\zeta_2) \cdot f(\zeta_2, \zeta_1)}{c_2} + \frac{\psi_2(\zeta_3) \cdot f(\zeta_3, \zeta_1)}{c_3} \\
&= \frac{-1 \cdot f(-1, 0)}{2} + \frac{1 \cdot f(1, 0)}{2};
\end{aligned}$$

and similarly, for b_{12}, we get

$$b_{12} = -\frac{f(0, -1)}{2} + \frac{f(0, 1)}{2}.$$

Coefficient b_{31} is given by

$$\begin{aligned}
b_{31} &= \frac{2}{3-1} \cdot \frac{1}{c_3 \cdot c_1} \sum_{j_1=1}^{3} \frac{\psi_3(\zeta_{j_1}) \cdot \psi_1(\zeta_1) \cdot f(\zeta_{j_1}, \zeta_1)}{c_{j_1}} \\
&= \frac{1}{2} \left[\frac{1 \cdot f(-1, 0)}{2} - f(0, 0) + \frac{1 \cdot f(1, 0)}{2} \right] \\
&= -\frac{f(0, 0)}{2} + \frac{f(-1, 0) + f(1, 0)}{4},
\end{aligned}$$

10

and b_{13} is obtained similarly

$$b_{13} = -\frac{f(0,0)}{2} + \frac{f(0,-1) + f(0,1)}{4}.$$

Formula (14) does not apply to a constant term b_{11}. To find b_{11}, observe that (13) implies

$$\widehat{f}^{2,1}(0,0;b) = $$
$$b_{11} + \frac{f(0,0)}{2} - \frac{f(-1,0) + f(1,0)}{4} + \frac{f(0,0)}{2} - \frac{f(0,-1) + f(0,1)}{4}.$$

Since under interpolation, we must have $\widehat{f}^{2,1}(0,0;b) = f(0,0)$, the last formula yields

$$b_{11} = \frac{f(-1,0) + f(1,0) + f(0,-1) + f(0,1)}{4}.$$

Note that to compute the coefficients, we need to evaluate function f in five Smolyak grid points of $\mathcal{H}^{2,1}$.

2.5   Shortcomings of the conventional Smolyak method

The conventional Smolyak method using nested sets is inefficient. First, it creates a list of tensor products with many repeated elements and then, it eliminates the repetitions. In high-dimensional applications, the number of repetitions is large and increases with both μ and d, which leads to a considerable increase in computational expense.

Repetitions of grid points can be appreciated by looking at Table 2. For example, when constructing $\mathcal{H}^{2,1}$, we list a grid point $(0,0)$ in three different cells, and hence, we must eliminate two grid points out of seven; when constructing $\mathcal{H}^{2,2}$, we must eliminate twelve repeated points out of twenty five points, etc. However, the repeated grid points are not a critical issue for the computational expense. Grid points must be constructed just once, and it is not so important if they are constructed efficiently or not. It is a one-time fixed cost.

Unfortunately, the Smolyak formula (5) involves the same kind of repetitions, and it is not a fixed cost. For example, $\widehat{f}^{2,1}$, given by (13), lists seven basis functions $\{1\}$, $\{1, \psi_2(x), \psi_3(x)\}$ and $\{1, \psi_2(y), \psi_3(y)\}$ in (8)–(10), respectively, and eliminates two repeated functions $\{1\}$ by assigning a weight (-1) to $p^{|2|}$; furthermore, $\widehat{f}^{2,2}$, derived in Appendix B, creates a list of twenty five basis functions and removes twelve repeated basis function by assigning appropriate weights, etc. We suffer from repetitions every time we evaluate a Smolyak polynomial function. This is an especially important issue in the context of numerical methods for solving dynamic economic models, since we must interpolate decision and value functions in a very large number of points, e.g., grid points, integration nodes and time periods. Moreover, we must repeat interpolation each time when the decision and value functions change in the iterative cycle. The overall cost of repetitions in the Smolyak formula can be very large.

3 Efficient implementation of the Smolyak method for interpolation

We have argued that Smolyak (1963) sparse-grid structure is an efficient choice for high-dimensional interpolation. However, the existing implementation of the Smolyak method does not arrive to this structure directly. Instead, it produces such a structure using a linear combinations of sets with repeated elements, which is inefficient and expensive. In this section, we propose a more efficient implementation of the Smolyak method that avoids costly repetitions of elements and arrives to the Smolyak structure directly. Our key novelty is to replace the conventional nested-set generators with equivalent disjoint-set generators. We use the disjoint-set generators not only for constructing the Smolyak grids but also for constructing the Smolyak basis functions; as a result, we do not make use of the conventional interpolation formula of type (7). Furthermore, to identify the interpolating coefficients, we use a canonical Lagrange interpolation; thus, we also do not make use of formula (14) for the coefficient. We find it easiest to present our implementation of the Smolyak method starting from a description of the Lagrange interpolation framework.

3.1 Multidimensional Lagrange interpolation

We consider the following interpolation problem. Let $f : [-1, 1]^d \to \mathbb{R}$ be a smooth function defined on a normalized d-dimensional hypercube, and let $\widehat{f}(\cdot; b)$ be a polynomial function of the form

$$\widehat{f}(x; b) = \sum_{n=1}^{M} b_n \Psi_n (x), \tag{15}$$

where $\Psi_n : [-1, 1]^d \to \mathbb{R}$, $n = 1, ..., M$, are d-dimensional basis functions, and $b \equiv (b_1, ..., b_M)$ is a coefficient vector.

We construct a set of M grid points $\{x_1, ..., x_M\}$ in $[-1, 1]^d$, and we compute b so that the true function, f, and its approximation, $\widehat{f}(\cdot; b)$ coincide in all grid points:

$$\begin{bmatrix} f(x_1) \\ \cdots \\ f(x_M) \end{bmatrix} = \begin{bmatrix} \widehat{f}(x_1; b) \\ \cdots \\ \widehat{f}(x_M; b) \end{bmatrix} = \begin{bmatrix} \Psi_1(x_1) & \cdots & \Psi_M(x_1) \\ \cdots & \ddots & \cdots \\ \Psi_1(x_M) & \cdots & \Psi_M(x_M) \end{bmatrix} \cdot \begin{bmatrix} b_1 \\ \cdots \\ b_M \end{bmatrix}. \tag{16}$$

Approximation $\widehat{f}(\cdot; b)$ is used to interpolate (infer, reconstruct) f in any point $x \in [-1, 1]^d$.

To implement the above interpolation method, we must perform three steps:

(i) Choose M grid points $\{x_1, ..., x_M\}$.

(ii) Choose M basis functions for forming $\widehat{f}(x; b)$.

(iii) Compute b that makes f and $\widehat{f}(\cdot; b)$ coincide in all grid points.

Lagrange interpolation allows for many different choices of grid points and basis functions. We will use grid points and basis functions produced by the Smolyak method. In Section 3.2, we construct the Smolyak grid points; in Section 3.3, we produce the Smolyak basis functions;

in Section [3.4], we identify the interpolation coefficients; in Section [3.5], we compare our implementation of the Smolyak method with the conventional implementation described in Section [2]; and finally, in Section [3.6], we show an efficient formula for Smolyak interpolation.

3.2 Construction of Smolyak grids using unidimensional disjoint sets

To construct a Smolyak grid, we proceed as in the conventional Smolyak method, namely, we produce sets of unidimensional grid points, compute tensor products of such sets and select an appropriate subsets of tensor-product elements for constructing a multidimensional grid. The difference is that we operate with unidimensional disjoint sets instead of unidimensional nested sets. This allows us to avoid repetitions of grid points.

3.2.1 Unidimensional disjoint sets of grid points

Let us define a sequence of disjoint sets $A_1, A_2, ...$ using the sequence of nested sets $S_1, S_2, ...$ of Section [2.2.1] such that $A_1 = S_1$ and $A_i = S_i \backslash S_{i-1}$ for $i \geq 2$:

$i = 1 : A_1 = \{0\};$

$i = 2 : A_2 = \{-1, 1\};$

$i = 3 : A_3 = \left\{ \frac{-1}{\sqrt{2}}, \frac{1}{\sqrt{2}} \right\};$

$i = 4 : A_4 = \left\{ \frac{-\sqrt{2+\sqrt{2}}}{2}, \frac{-\sqrt{2-\sqrt{2}}}{2}, \frac{\sqrt{2-\sqrt{2}}}{2}, \frac{\sqrt{2+\sqrt{2}}}{2} \right\}.$

By definition, A_i is a set of points in S_i but not in S_{i-1}. The constructed sets are disjoint, $A_i \cap A_j = \{\varnothing\}$ for any $i \neq j$ and their unions satisfy $A_1 \cup ... \cup A_i = S_i$. The number of elements in A_i is $m(i) - m(i-1) = 2^{i-2}$ points for $i \geq 3$, and the number of elements in A_1 and A_2 is 1 and 2, respectively.

3.2.2 Tensor products of unidimensional disjoint sets of points

Next, we construct tensor products of disjoint sets of unidimensional grid points. Again, we consider the two-dimensional case, with $i = 1, 2, 3$ in each dimension.

In Table [3], indices i_1 and i_2 are indices that correspond to dimensions one and two, respectively; a column A_{i_1} and a row A_{i_2} (see $A_{i_1} \backslash A_{i_2}$) show the sets of unidimensional elements that correspond to dimensions one and two, respectively; (ζ_ℓ, ζ_n) denotes a two-dimensional grid point obtained by combining a grid point ζ_ℓ in dimension 1 and a grid point ζ_n in dimension two. Thus, the table shows incremental grid points, and we can easily see which grid points are added when we increase the approximation level.

3.2.3 Smolyak sparse grids

We use the same Smolyak rule [1] for constructing multidimensional grid points. That is, we select elements that belong to the cells in Table [3] for which the sum of indices of a column and a row, $i_1 + i_2$, is between d and $d + \mu$. This leads to the same Smolyak grids $\mathcal{H}^{2,0}$, $\mathcal{H}^{2,1}$ and $\mathcal{H}^{2,2}$ as shown in [2], [3], and [4], respectively. However, in our case, no grid point is repeated

Table 3: Tensor products of disjoint sets of unidimensional grid points for the two-dimensional case

		$i_2 = 1$	$i_2 = 2$	$i_2 = 3$
	$A_{i_1} \backslash A_{i_2}$	0	$-1, 1$	$\frac{-1}{\sqrt{2}}, \frac{1}{\sqrt{2}}$
$i_1 = 1$	0	$(0,0)$	$(0,-1),(0,1)$	$\left(0, \frac{-1}{\sqrt{2}}\right), \left(0, \frac{1}{\sqrt{2}}\right)$
$i_1 = 2$	$\begin{matrix}-1\\1\end{matrix}$	$\begin{matrix}(-1,0)\\(1,0)\end{matrix}$	$\begin{matrix}(-1,-1),(-1,1)\\(1,-1),(1,1)\end{matrix}$	$\begin{matrix}\left(-1, \frac{-1}{\sqrt{2}}\right), \left(-1, \frac{1}{\sqrt{2}}\right)\\\left(1, \frac{-1}{\sqrt{2}}\right), \left(1, \frac{1}{\sqrt{2}}\right)\end{matrix}$
$i_1 = 3$	$\begin{matrix}\frac{-1}{\sqrt{2}}\\\frac{1}{\sqrt{2}}\end{matrix}$	$\begin{matrix}\left(\frac{-1}{\sqrt{2}},0\right)\\\left(\frac{1}{\sqrt{2}},0\right)\end{matrix}$	$\begin{matrix}\left(\frac{-1}{\sqrt{2}},-1\right),\left(\frac{-1}{\sqrt{2}},1\right)\\\left(\frac{1}{\sqrt{2}},-1\right),\left(\frac{1}{\sqrt{2}},1\right)\end{matrix}$	$\begin{matrix}\left(\frac{-1}{\sqrt{2}}, \frac{-1}{\sqrt{2}}\right), \left(\frac{-1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)\\\left(\frac{1}{\sqrt{2}}, \frac{-1}{\sqrt{2}}\right), \left(\frac{1}{\sqrt{2}}, \frac{1}{\sqrt{2}}\right)\end{matrix}$

in Table 3. Furthermore, note that the multidimensional grids $\mathcal{H}^{2,0}$, $\mathcal{H}^{2,1}$ and $\mathcal{H}^{2,2}$ are nested $\mathcal{H}^{2,0} \subset \mathcal{H}^{2,1} \subset \mathcal{H}^{2,2}$ even though their unidimensional generators are disjoint (not nested).

3.3 Construction of Smolyak polynomials using unidimensional disjoint sets

Our construction of Smolyak polynomials parallels our construction of Smolyak grids using unidimensional disjoint sets. To be specific, we produce disjoint sets of unidimensional basis functions, compute tensor products of such sets and select an appropriate subset of tensor-product elements for constructing a multidimensional polynomial function. Again, using disjoint-set generators instead of nested-set generators allows us to avoid repetitions of basis functions.

3.3.1 Unidimensional disjoint sets of basis functions

We first construct disjoint sets $A_1, ..., A_i, ...$ that contain unidimensional basis functions:
$i = 1 : A_1 = \{1\}$;
$i = 2 : A_2 = \{\psi_2(x), \psi_3(x)\}$;
$i = 3 : A_3 = \{\psi_4(x), \psi_5(x)\}$.
$i = 4 : A_3 = \{\psi_6(x), \psi_7(x), \psi_8(x), \psi_9(x)\}$.

3.3.2 Tensor products of unidimensional disjoint sets of basis functions

We next construct the two-dimensional basis functions using tensor products of unidimensional basis functions.

By construction, all elements in Table 4 appear just once and therefore, are non-repeated. Note that Table 4 looks exactly like Table 3.

Table 4: Tensor products of disjoint sets of Chebyshev polynomial basis for the two-dimensional case

	$A_{i_1}\backslash A_{i_2}$	$i_2 = 1$: 1	$i_2 = 2$: $\psi_2(y),\psi_3(y)$	$i_2 = 3$: $\psi_4(y),\psi_5(y)$
$i_1 = 1$	1	1	$\psi_2(y),\psi_3(y)$	$\psi_4(y),\psi_5(y)$
$i_1 = 2$	$\psi_2(x)$ $\psi_3(x)$	$\psi_2(x)$ $\psi_3(x)$	$\psi_2(x)\psi_2(y),\psi_2(x)\psi_3(y)$ $\psi_3(x)\psi_2(y),\psi_3(x)\psi_3(y)$	$\psi_2(x)\psi_4(y),\psi_2(x)\psi_5(y)$ $\psi_3(x)\psi_4(y),\psi_3(x)\psi_5(y)$
$i_1 = 3$	$\psi_4(x)$ $\psi_5(x)$	$\psi_4(x)$ $\psi_5(x)$	$\psi_4(x)\psi_2(y),\psi_4(x)\psi_3(y)$ $\psi_5(x)\psi_2(y),\psi_5(x)\psi_3(y)$	$\psi_4(x)\psi_4(y),\psi_4(x)\psi_5(y)$ $\psi_5(x)\psi_4(y),\psi_5(x)\psi_5(y)$

3.3.3 Smolyak polynomial basis functions

We apply the same Smolyak rule (1) to produce a list of basis function as we used for producing grid points. Let $\mathcal{P}^{d,\mu}$ denote a Smolyak basis function with dimensionality d and approximation level μ.

- If $\mu = 0$, then $2 \le i_1 + i_2 \le 2$. The only cell that satisfies this restriction is $i_1 = 1$ and $i_2 = 1$, so that the set of Smolyak basis functions has just one element

$$\mathcal{P}^{2,0} = \{1\}. \tag{17}$$

- If $\mu = 1$, then $2 \le i_1 + i_2 \le 3$. The three cells that satisfy this restriction are (a) $i_1 = 1$, $i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$, and the corresponding five Smolyak basis functions are

$$\mathcal{P}^{2,1} = \{1, \psi_2(x), \psi_3(x), \psi_2(y), \psi_3(y)\}. \tag{18}$$

- If $\mu = 2$, then $2 \le i_1 + i_2 \le 4$. There are six cells that satisfy this restriction: (a) $i_1 = 1$, $i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$; (d) $i_1 = 1$, $i_2 = 3$; (e) $i_1 = 2$, $i_2 = 2$; (f) $i_1 = 3$, $i_2 = 1$, and there are thirteen Smolyak basis functions

$$\mathcal{P}^{2,2} = \{1, \psi_2(x), \psi_3(x), \psi_2(y), \psi_3(y), \psi_4(x), \psi_5(x), \psi_4(y), \psi_5(y)$$
$$\psi_2(x)\psi_2(y), \ \psi_2(x)\psi_3(y), \ \psi_3(x)\psi_2(y), \ \psi_3(x)\psi_3(y)\}. \tag{19}$$

The sets of Smolyak basis functions $\mathcal{P}^{2,0}$, $\mathcal{P}^{2,1}$ and $\mathcal{P}^{2,2}$ defined in (17), (18), and (19) correspond to grids $\mathcal{H}^{2,0}$, $\mathcal{H}^{2,1}$ and $\mathcal{H}^{2,2}$ defined in (2), (3), and (4), respectively. To form a Smolyak polynomial function under our construction, one just need to use the elements satisfying condition (1) since no element is repeated in Table 4 by construction.

3.4 Construction of Smolyak coefficients using Lagrange interpolation

Recall that $b_{\ell_1\ldots\ell_d}$'s in (5) must be constructed so that the Smolyak polynomial $\widehat{f}^{d,\mu}$ matches the true function f on the Smolyak grid $\mathcal{H}^{d,\mu}$. We construct the Smolyak interpolating coefficients solving the inverse problem (16) numerically.

3.4.1 Solution to the inverse problem

Provided that the matrix of basis functions in the right side of (16) has full rank, we obtain a system of M linear equations with M unknowns that admits a unique solution for b :

$$
\begin{bmatrix} b_1 \\ \cdots \\ b_M \end{bmatrix} = \begin{bmatrix} \Psi_1(x_1) & \cdots & \Psi_M(x_1) \\ \cdots & \ddots & \cdots \\ \Psi_1(x_M) & \cdots & \Psi_M(x_M) \end{bmatrix}^{-1} \begin{bmatrix} f(x_1) \\ \cdots \\ f(x_M) \end{bmatrix}. \tag{20}
$$

By construction, the approximating polynomial $\widehat{f}$ coincides with the true function f in all grid points, i.e., $\widehat{f}(x_n; b) = f(x_n)$ for all $x_n \in \{x_1, ..., x_M\}$.

3.4.2 Example of interpolation coefficients under $d = 2$ and $\mu = 1$ revisited

Let us now construct the Smolyak polynomial coefficients under $d = 2$ and $\mu = 1$ by solving the inverse problem as shown in (20). We again use unidimensional Chebyshev polynomials and extrema of Chebyshev polynomials. As follows from (18), the Smolyak polynomial function is given by

$$
\widehat{f}(x, y; b) \equiv b_{11} \cdot 1 + b_{21}x + b_{31}\left(2x^2 - 1\right) + b_{12}y + b_{13}\left(2y^2 - 1\right), \tag{21}
$$

where $b \equiv (b_{11}, b_{21}, b_{31}, b_{12}, b_{13})$ is a vector of five unknown coefficients on five basis functions. We identify the coefficients such that the approximation $\widehat{f}(x, y; b)$ matches the true function $f(x, y)$ in five Smolyak grid points distinguished in (3), namely, $\{(0, 0), (-1, 0), (1, 0), (0, -1), (0, 1)\}$.

This yields a system of linear equations $Bb = w$, where

$$
\mathcal{B} \equiv \begin{bmatrix} 1 & 0 & -1 & 0 & -1 \\ 1 & -1 & 1 & 0 & -1 \\ 1 & 1 & 1 & 0 & -1 \\ 1 & 0 & -1 & -1 & 1 \\ 1 & 0 & -1 & 1 & 1 \end{bmatrix}; \quad b \equiv \begin{bmatrix} b_{11} \\ b_{21} \\ b_{31} \\ b_{12} \\ b_{13} \end{bmatrix}; \quad w \equiv \begin{bmatrix} f(0,0) \\ f(-1,0) \\ f(1,0) \\ f(0,-1) \\ f(0,1) \end{bmatrix}. \tag{22}
$$

The solution to this system is given by $b = \mathcal{B}^{-1}w$,

$$
\begin{bmatrix} b_{11} \\ b_{21} \\ b_{31} \\ b_{12} \\ b_{13} \end{bmatrix} = \begin{bmatrix} 0 & \frac{1}{4} & \frac{1}{4} & \frac{1}{4} & \frac{1}{4} \\ 0 & -\frac{1}{2} & \frac{1}{2} & 0 & 0 \\ -\frac{1}{2} & \frac{1}{4} & \frac{1}{4} & 0 & 0 \\ 0 & 0 & 0 & -\frac{1}{2} & \frac{1}{2} \\ -\frac{1}{2} & 0 & 0 & \frac{1}{4} & \frac{1}{4} \end{bmatrix} \begin{bmatrix} f(0,0) \\ f(-1,0) \\ f(1,0) \\ f(0,-1) \\ f(0,1) \end{bmatrix} = \begin{bmatrix} \frac{f(-1,0)+f(1,0)+f(0,-1)+f(0,1)}{4} \\ \frac{-f(-1,0)+f(1,0)}{2} \\ -\frac{f(0,0)}{2} + \frac{f(-1,0)+f(1,0)}{4} \\ \frac{-f(0,-1)+f(0,1)}{2} \\ -\frac{f(0,0)}{2} + \frac{f(0,-1)+f(0,1)}{4} \end{bmatrix} \tag{23}
$$

As expected, coefficients in (23) coincide with those produced by conventional formula (14).

3.5 Comparison to the conventional Smolyak method

We compare our implementation of the Smolyak method with the conventional implementation described in Section 2. First, we quantify the reduction in cost of the Smolyak interpolant evaluation that we achieve by avoiding the repetitions and then, we compare the Lagrange interpolation method with explicit formulas for the interpolating coefficients.

3.5.1 Nested-set versus disjoint-set constructions of the Smolyak interpolant

First, consider the conventional construction of the Smolyak polynomial in (5) based on unidimensional nested sets; see Section 2.3.1. By (5), the number of terms which we list to evaluate $\widehat{f}^{d,\mu}$ is $\sum\limits_{\max(d,\mu+1)\leq|i|\leq d+\mu}\prod\limits_{j=1}^{d}m\left(i_{j}\right)$. Note that the counting coefficient $(-1)^{d+\mu-|i|}\binom{d-1}{d+\mu-|i|}$ is not relevant for computation of the number of terms because it does not add new terms but only counts the number of repetitions to be cancelled out.

Second, consider our alternative construction of the Smolyak polynomial function based on unidimensional disjoint sets; see Section 3.3. The number of basis functions in $\mathcal{P}^{d,\mu}$ is equal to $\sum\limits_{d\leq|i|\leq d+\mu}\prod\limits_{j=1}^{d}[m\left(i_{j}\right)-m\left(i_{j}-1\right)]$. To assess the difference in costs between the two constructions, we consider the ratio of the number of terms under the two constructions:

$$R^{d,\mu}\equiv\frac{\sum\limits_{\max(d,\mu+1)\leq|i|\leq d+\mu}\prod\limits_{j=1}^{d}m\left(i_{j}\right)}{\sum\limits_{d\leq|i|\leq d+\mu}\prod\limits_{j=1}^{d}[m\left(i_{j}\right)-m\left(i_{j}-1\right)]}=\frac{\sum\limits_{\max(d,\mu+1)\leq|i|\leq d+\mu}\prod\limits_{j=1}^{d}m\left(i_{j}\right)}{\sum\limits_{d\leq|i|\leq d+\mu}\prod\limits_{j=1}^{d}m\left(i_{j}\right)\prod\limits_{j=1}^{d}\left(1-\frac{m(i_{j}-1)}{m(i_{j})}\right)}. \quad (24)$$

In Figure 2, we represent the ratio $R^{d,\mu}$ for $1\leq d\leq 30$ and $0\leq\mu\leq 5$. The higher is the level of approximation, the larger are the savings due to more efficient evaluation of the Smolyak interpolant. In particular, under $\mu=1$ the conventional nested-set construction of the Smolyak interpolant is 40 percent more expensive than our construction, while under $\mu=6$, it is more than 700 percent more expensive than ours. We shall emphasize that our construction saves on cost every time when the Smolyak interpolant is evaluated, i.e., in every grid point, integration node or time period.

Some qualitative assessment of $R^{d,\mu}$ can be derived for the case when $\max(d,\mu+1)=d$ (this is the most relevant case for high-dimensional problems in which high-order polynomial approximations are infeasible). Consider the term $\prod\limits_{j=1}^{d}\left(1-\frac{m(i_{j}-1)}{m(i_{j})}\right)$ in the denominator of (24).

If $i_{j}=1$, we have $1-\frac{m(0)}{m(1)}=1$, and if $i_{j}\geq 2$, we have $1-\frac{m(i_{j}-1)}{m(i_{j})}=\left(1-\frac{2^{i_{j}-2}+1}{2^{i_{j}-1}+1}\right)=\frac{2^{i_{j}-2}}{2^{i_{j}-1}+1}$. Observe that $\frac{1}{2}\leq\frac{2^{i_{j}-2}}{2^{i_{j}-1}+1}\leq\frac{2}{3}$ for $i_{j}\geq 2$, and that the limits are reached under $i_{j}\rightarrow\infty$ and $i_{j}=2$, respectively. This means that for any $i_{j}\geq 2$, our disjoint-set construction reduces the number of terms by at least a factor of $\frac{1}{2}$ compared to the conventional nested-set construction.

Figure 2: The ratio of the number of basis functions under two alternative implementations of the Smolyak method.
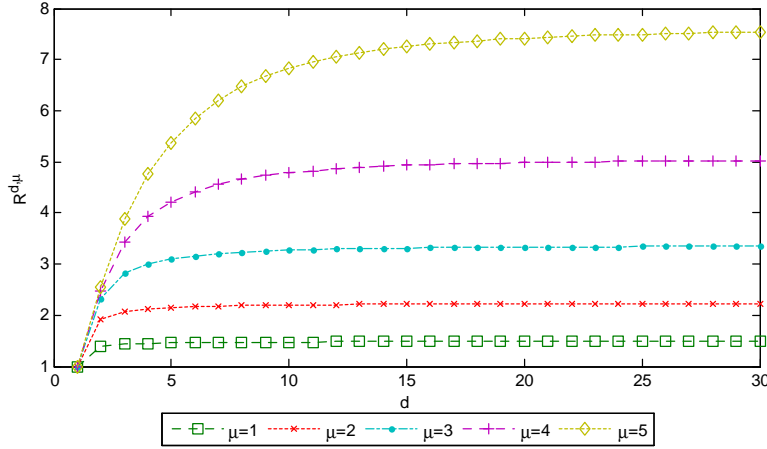

3.5.2 Analytical expression for interpolation coefficients versus numerical Lagrange interpolation

The Lagrange interpolation method is universal: it can be applied to any sets of grid points and basis functions provided that the inverse problem (20) is well-defined (the matrix of basis functions evaluated in grid points has full rank). In turn, the formula of type (14) is a special case of Lagrange interpolation in which the solution to the inverse problem can be derived in a closed form. The numerical implementation of Lagrange interpolation using (20) has two potential shortcomings compared to the closed-form expression: first, it can be numerically unstable and second, it can be expensive.

To attain numerical stability, we must use families of grid points and basis functions that do not lead to ill-conditioned inverse problems. Chebyshev polynomials and their extrema are one example but many other choices are possible.[4]

To reduce the computational expense, we use the following precomputation technique in the context of numerical algorithm for solving dynamic economic models. We compute the inverse of the matrix of basis functions in (20) at the initialization stage, before entering the main iterative cycle. In this way, the expensive part of Lagrange interpolation becomes a fixed cost. In the main iterative cycle, computing the interpolation coefficients requires only inexpensive matrix multiplications, which can be easily parallelized for a further reduction in cost if needed. This precomputation technique allows us to reconstruct the polynomial coefficients at a low cost each time when decision and value functions change along iterations.[5]

---

[4]See Judd et al. (2011) for a discussion of numerical techniques for dealing with ill-conditioned problems.

[5]See Maliar et al. (2011) and Judd et al. (2011) for other precomputation techniques that reduce the computational expense of numerical solution methods, precomputation of intertemporal choice functions and precomputation of integrals, respectively.

3.6 Smolyak formula for interpolation revisited

It is relatively straightforward to write a computer code that automates the construction of the Smolyak interpolant under our disjoint-set generators described in Section 3.3. We just have to sum up all the basis functions that appear in the table like Table 4 since no basis function is repeated by construction. Nonetheless, we were also able to derive a formula for Smolyak interpolation using disjoint sets, which is parallel to the conventional formula (5) using nested sets. We show such a formula below.

3.6.1 Smolyak polynomial: efficient construction

The formula for constructing a Smolyak polynomial function using unidimensional disjoint sets is as follows:

$$\widehat{f}^{d,\mu}(x_1, ..., x_d; b) = \sum_{d \leq |i| \leq d+\mu} q^{|i|}(x_1, ..., x_d);$$ (25)

for each $|i|$ satisfying $d \leq |i| \leq d + \mu$, a tensor-product operator $p^{|i|}(x_1, ..., x_d)$ is defined as

$$q^{|i|}(x_1, ..., x_d) = \sum_{i_1 + ... + i_d = |i|} q^{i_1, ..., i_d}(x_1, ..., x_d),$$ (26)

and $q^{i_1, ..., i_d}(x_1, ..., x_d)$ is defined as

$$q^{i_1, ..., i_d}(x_1, ..., x_d) = \sum_{\ell_1 = m(i_1 - 1) + 1}^{m(i_1)} ... \sum_{\ell_d = m(i_d - 1) + 1}^{m(i_d)} b_{\ell_1 ... \ell_d} \psi_{\ell_1}(x_1) \cdots \psi_{\ell_d}(x_d),$$ (27)

where $\psi_{\ell_1}(x_1), ..., \psi_{\ell_d}(x_d)$ are unidimensional basis functions, in dimensions $1, ..., d$, respectively; $\psi_{\ell_1}(x_1) \cdots \psi_{\ell_d}(x_d)$ is a d-dimensional basis function; $\ell_d = 1, ..., m(i_d)$; $b_{\ell_1 ... \ell_d}$ are coefficients vectors. We use the convention that $m(0) = 0$ and $m(1) = 1$. By construction of (27), there are no repeated terms across different $q^{i_1, ..., i_d}$'s.

Formula (25) sums up all the terms in Table 4 (recall that all the sets in Table 4 are disjoint and basis functions are never repeated by construction). The economization from our more efficient alternative Smolyak formula is described by (24) and is shown in Figure 2. To compute coefficients $b_{\ell_1 ... \ell_d}$'s, we can use either the conventional closed-form expression (14) or a numerical solution (20) to the Lagrange interpolation problem.

3.6.2 Example of Smolyak polynomial under $d = 2$ and $\mu = 1$ revisited

We now illustrate the construction of Smolyak polynomial function (25) by revisiting an example with $d = 2$ and $\mu = 1$ studied in Section 2.3.2 (in Appendix B, we also show the construction of such a function with $d = 2$ and $\mu = 2$).

For the case of $\mu = 1$, we have $i_1 + i_2 \leq 3$. This restriction is satisfied in three cases: (a)

$i_1 = i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$. Thus, using (27), we obtain

$$\text{(a) } q^{1,1} = \sum_{\ell_1=m(0)+1}^{m(1)} \sum_{\ell_2=m(0)+1}^{m(1)} b_{\ell_1\ell_2} \psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{11}, \tag{28}$$

$$\text{(b) } q^{1,2} = \sum_{\ell_1=m(0)+1}^{m(1)} \sum_{\ell_2=m(1)+1}^{m(2)} b_{\ell_1\ell_2} \psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{12}\psi_2(y) + b_{13}\psi_3(y), \tag{29}$$

$$\text{(c) } q^{2,1} = \sum_{\ell_1=m(1)+1}^{m(2)} \sum_{\ell_2=m(0)+1}^{m(1)} b_{\ell_1\ell_2} \psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{21}\psi_2(x) + b_{31}\psi_3(x). \tag{30}$$

Collecting elements q^{i_1,i_2} with the same $i_1 + i_2 \equiv |i|$, we have

$$q^{|2|} \equiv q^{1,1}, \tag{31}$$

and

$$q^{|3|} \equiv q^{2,1} + q^{1,2}. \tag{32}$$

Smolyak polynomial function (27) for the case of $\mu = 1$ is given by

$$\mathcal{P}^{2,1}(x, y; b) = \sum_{|i| \leq d+\mu} q^{|i|} = q^{1,1} + q^{2,1} + q^{1,2}$$

$$= b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x) + b_{12}\psi_2(y) + b_{13}\psi_3(y). \tag{33}$$

This formula coincides with (13). Thus, we obtain the same Smolyak polynomial function as the one produced by the conventional Smolyak formula but we avoid forming lists of repeated basis functions.

4 Anisotropic Smolyak method

In economic applications, variables often enter assymetically in decision functions or value functions. For example, in a heterogeneous-agent economy studied in Kollmann et al. (2011), the individual choices depend more on her own variables than on variables of other agents; and the literature, based on Tauchen and Hussy's (1991) discretizations uses many grid points for endogenous state variables and few grid points for exogenous state variables.

However, the Smolyak method, studied in Sections 2 and 3, treats all dimensions equally in the sense that it uses the same number of grid points and basis functions for all variables. To increase the quality of approximation under such a method, we must equally increase the number of grid points and basis functions in all dimensions. This may be too costly to do in large-scale applications. An alternative is to increase the number of grid points and basis functions only in those dimensions that are most important for the overall quality of approximation. In this section, we show a variant of the Smolyak method that allows for a differential treatment of variables, specifically, it enables us to separately choose accuracy levels for each dimension by taking into account a specific structure of decision functions in a given economic model. We refer to such a method as a *Smolyak method with anisotropic grid*.

4.1   Definition of anisotropy

The term *anisotropic* comes from mathematical literature and refers to functions that are "asymmetric" in some respect, for example, have more curvature in some variables than in others, or have a larger range in some variables than in others. Gerstner and Griebel (2003) propose dimension-adaptive grids for numerical integration of multivariate anisotropic functions; see also Bungartz and Griebel (2004) and Garcke (2011).

The above literature uses very flexible piecewise linear basis functions which allows for consecutive refinements of the solution in those areas in which higher accuracy is needed (though at a high computational expense). Our method, based on a global polynomial approximation, is less flexible, and the possibility of refinement is limited to specific dimensions. Our implementation of the anisotropic construction and the error bounds are therefore different from those in the literature that uses piecewise basis functions.

As a starting point, consider a standard (isotropic) Smolyak grid with a degree of approximation μ as defined in Sections 2 and 3. Observe that for each dimension $j = 1, ..., d$, index i_j varies from 1 to $\mu + 1$. For example, in Table 2, i_1 and i_2 vary from 1 to 3, and μ varies from 0 to 2, respectively (i.e., μ is equal to the maximum i_j, $j = 1, ..., d$, minus 1).

For the anisotropic case, let us denote by μ_j an approximation level in dimension j. If in a dimension j, the maximum index admitted is $i_j^{\max}$, i.e., $i_j = 1, ..., i_j^{\max}$, then $\mu_j = i_j^{\max} - 1$. A Smolyak grid is called *anisotropic* if there is at least one dimension j such that $\mu_j \neq \mu_k$ for all $k \neq j$; otherwise, it is called *isotropic*. We denote an anisotropic Smolyak grid, Smolyak basis functions and Smolyak interpolant as $\mathcal{H}^{d,(\mu_1,...,\mu_d)}$, $\mathcal{P}^{d,(\mu_1,...,\mu_d)}$ and $\widehat{f}^{d,(\mu_1,...,\mu_d)}$, respectively.

4.2   Anisotropic Smolyak grid

Our design of an anisotropic variant of the Smolyak method parallels the design of the isotropic Smolyak method described in Sections 3. Namely, we first produce an anisotropic Smolyak grid, we then produce an anisotropic Smolyak polynomial function, and we finally compute polynomial coefficients using Lagrange interpolation. Our anisotropic construction also builds on disjoint-set generators, which allows us to avoid costly repetitions of elements in the Smolyak interpolant.

4.2.1   Tensor products of unidimensional sets of points

The two-dimensional tensor products constructed from the unidimensional sets up to $i = 4$ and $i = 2$ in the dimensions x and y, respectively are summarized in Table 5. By construction, the table contains only non-repeated elements.

4.2.2   Smolyak sets of multidimensional elements under anisotropic construction

The Smolyak rule tells us which tensor products must be selected. For the two-dimensional case, it is as follows: Select elements that belong to the cells in Table 5 for which the following

Table 5: Tensor products of unidimensional disjoint sets of grid points in the two-dimensional case

		$i_2 = 1$	$i_2 = 2$
	$A_{i_1}\backslash A_{i_2}$	0	$-1, 1$
$i_1 = 1$	0	$(0,0)$	$(0,-1),(0,1)$
$i_1 = 2$	-1 1	$(-1,0)$ $(1,0)$	$(-1,-1),(-1,1)$ $(1,-1),(1,1)$
$i_1 = 3$	$\frac{-1}{\sqrt{2}}$ $\frac{1}{\sqrt{2}}$	$\left(\frac{-1}{\sqrt{2}},0\right)$ $\left(\frac{1}{\sqrt{2}},0\right)$	$\left(\frac{-1}{\sqrt{2}},-1\right),\left(\frac{-1}{\sqrt{2}},1\right)$ $\left(\frac{1}{\sqrt{2}},-1\right),\left(\frac{1}{\sqrt{2}},1\right)$
$i_1 = 4$	$\frac{-\sqrt{2+\sqrt{2}}}{2}$ $\frac{-\sqrt{2-\sqrt{2}}}{2}$ $\frac{\sqrt{2-\sqrt{2}}}{2}$ $\frac{\sqrt{2+\sqrt{2}}}{2}$	$\left(\frac{-\sqrt{2+\sqrt{2}}}{2},0\right)$ $\left(\frac{-\sqrt{2-\sqrt{2}}}{2},0\right)$ $\left(\frac{\sqrt{2-\sqrt{2}}}{2},0\right)$ $\left(\frac{\sqrt{2+\sqrt{2}}}{2},0\right)$	$\left(\frac{-\sqrt{2+\sqrt{2}}}{2},-1\right),\left(\frac{-\sqrt{2+\sqrt{2}}}{2},1\right)$ $\left(\frac{-\sqrt{2-\sqrt{2}}}{2},-1\right),\left(\frac{-\sqrt{2-\sqrt{2}}}{2},1\right)$ $\left(\frac{\sqrt{2-\sqrt{2}}}{2},-1\right),\left(\frac{\sqrt{2-\sqrt{2}}}{2},1\right)$ $\left(\frac{\sqrt{2+\sqrt{2}}}{2},-1\right),\left(\frac{\sqrt{2+\sqrt{2}}}{2},1\right)$

condition is satisfied

$$d \leq i_1 + i_2 \leq d + \mu^{\max}, \tag{34}$$
$$i_1 \leq \mu_1 + 1, \ i_2 \leq \mu_2 + 1, \tag{35}$$

where $\mu^{\max} \equiv \max\{\mu_1, \mu_2\}$ is a maximum of the level of approximation across the two dimensions, and the dimensionality is $d = 2$. In other words, the sum of indices of a column and a row, $i_1 + i_2$, must be between d and $d + \mu^{\max}$ subject to additional dimension-specific restrictions $i_1 \leq \mu_1 + 1, \ i_2 \leq \mu_2 + 1$.

Let us construct examples of Smolyak anisotropic grids using the anisotropic version of the Smolyak rule (34).

- If $(\mu_1, \mu_2) = (1, 0)$, then $\mu^{\max} = 1$ and the anisotropic Smolyak rule implies $2 \leq i_1 + i_2 \leq 3$, $i_1 \leq 2$ and $i_2 \leq 1$. The three cells that satisfy this restriction are (a) $i_1 = 1$, $i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$, and the corresponding three Smolyak grid points are

$$\mathcal{H}^{2,(1,0)} = \{(0,0), (-1,0), (1,0)\}. \tag{36}$$

- If $(\mu_1, \mu_2) = (2, 1)$, then $\mu^{\max} = 2$ and $2 \leq i_1 + i_2 \leq 4$, $i_1 \leq 3$ and $i_2 \leq 2$. There are five cells that satisfy this restriction (a) $i_1 = 1$, $i_2 = 1$; (b) $i_1 = 1$, $i_2 = 2$; (c) $i_1 = 2$, $i_2 = 1$; (d) $i_1 = 1$, $i_2 = 3$; (e) $i_1 = 2$, $i_2 = 2$; and there are eleven Smolyak grid points

$$\mathcal{H}^{2,(2,1)} = \big\{(-1,1), (0,1), (1,1), (-1,0), (0,0), (1,0), (-1,-1), (0,-1),$$
$$(1,-1), (\frac{-1}{\sqrt{2}},0), (\frac{1}{\sqrt{2}},0)\big\}. \tag{37}$$

- If $(\mu_1, \mu_2) = (3, 1)$, then $\mu^{\max} = 3$ and $2 \leq i_1 + i_2 \leq 5$, , $i_1 \leq 4$ and $i_2 \leq 2$. There are seven cells in the table that satisfy this restriction, and $\mathcal{H}^{3,(3,1)}$ consists of nineteen grid points (see Table 5).

The three Smolyak anisotropic grids constructed in the above two-dimensional example are shown in Figure 3.

Figure 3: Examples of Smolyak anisotropic grids

We do not elaborate the construction of the anisotropic Smolyak polynomial function because such a construction trivially repeats the construction of grid points. Furthermore, to find the interpolation coefficients, we use the Lagrange interpolation approach described in Section 3.4, which applies to anisotropic construction without changes. Finally, we can adapt Smolyak interpolation formula (25) to the anisotropic case by imposing restrictions on $i_1, ..., i_d$.

4.3   Advantages of anisotropic Smolyak method

The anisotropic class of methods involves a trade-off: from one side, reducing a number of grid points and basis functions, reduces the computational expense but from the other side, it also reduces the quality of approximation. This trade-off suggests that anisotropic methods must be used when the former effect overweighs the latter. Using anisotropic methods in practice would require us either to have certain knowledge of function that we want to interpolate or to do some experimentation. Namely, we can keep adding or removing grid points and basis functions in different dimensions until the target level of accuracy is attained. Maliar et al. (2013) provide the error bounds for the Smolyak anisotropic constructions.

Let us compare the number of elements in an isotropic Smolyak grid $\mathcal{H}^{d,\mu}$ with the number of elements in an anisotropic Smolyak grid $\mathcal{H}^{d,(\mu_1,...,\mu_d)}$; we assume that $\mu = \max\{\mu_1, ..., \mu_d\}$;

and in both cases, we use disjoint-set construction with no elements repeated

$$R^{d,\mu} = \frac{\sum\limits_{d \leq |i| \leq d+\mu} \prod\limits_{j=1}^{d} m\left(i_j\right)\left(1 - \frac{m(i_j-1)}{m(i_j)}\right)}{\sum\limits_{d \leq |i| \leq d+\mu, \left\{i_j \leq \mu_j+1\right\}_{j=1}^{d}} \prod\limits_{j=1}^{d} m\left(i_j\right)\left(1 - \frac{m(i_j-1)}{m(i_j)}\right)}.$$

The above ratio depends on the specific assumption about the approximation level in each dimension $(\mu_1, ..., \mu_d)$. Let us assume that the true function is completely flat in all dimensions except of dimension 1. To accurately approximate such a function, we can use an anisotropic Smolyak method in which $\mu_1 = \mu$ in dimension 1 and $\mu_j = 0$ for all other dimensions, $j = 2, ..., d$. In Figure 4, we show the corresponding ratio of the number of points under isotropic and anisotropic versions of the Smolyak method.

Figure 4: The ratio of the number of basis functions under isotropic and anisotropic versions of the Smolyak method.
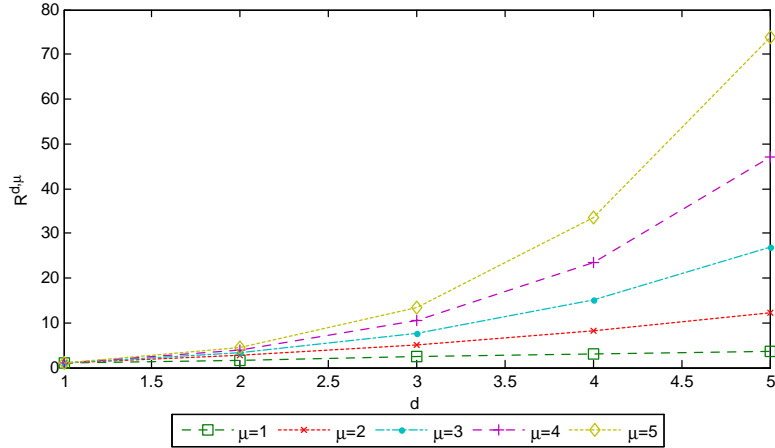

In this example, the savings are very large when d and μ are large. For example, when $d = 5$ and $\mu = 5$, the number of grid points and basis functions is reduced by nearly two orders of magnitude. This is an extreme example which shows maximum possible gains from anisotropy. In empirically relevant examples, the gains from anisotropic constructions can vary depending on the anisotropy of specific decision or value functions in economic models.

5   Smolyak method with adaptive domain

The Smolyak construction tells us how to represent and interpolate functions defined on a normalized d-dimensional hypercube. However, the solution domain of a typical dynamic economic model does not have the shape of a hypercube but can be a set of any shape in a d-dimensional

24

space. We now describe how to effectively adapt a multidimensional Smolyak hypercube to an unstructured solution domain of a given economic model.

5.1   Adaptive parallelotope

The ergodic set (i.e., the support of the ergodic distribution) of a dynamic economic model can have any shape in a d-dimensional space. It may be even an unbounded set such as $\mathbb{R}_+^d$. We must first construct a d-dimensional parallelotope to enclose the relevant area of the state space of the studied model, typically, a high-probability area of the ergodic set. We must then match the parallelotope to a normalized hypercube $[-1,1]^d$ used by the Smolyak method.

As an example, in Figure 5, we plot a simulation of 10,000 observations for capital and productivity level in a representative-agent neoclassical stochastic growth model with a closed-form solution (see Section 6.1 for a detailed description of this model).

We show two possible rectangulars in the figure that enclose a given set of simulated point: one is a conventional rectangular in the original coordinates, and the other is a rectangular obtained after a change of variables (both rectangulars are minimized subject to including all simulated points).

Figure 5: Two rectangular domains enclosing a set of simulated points.
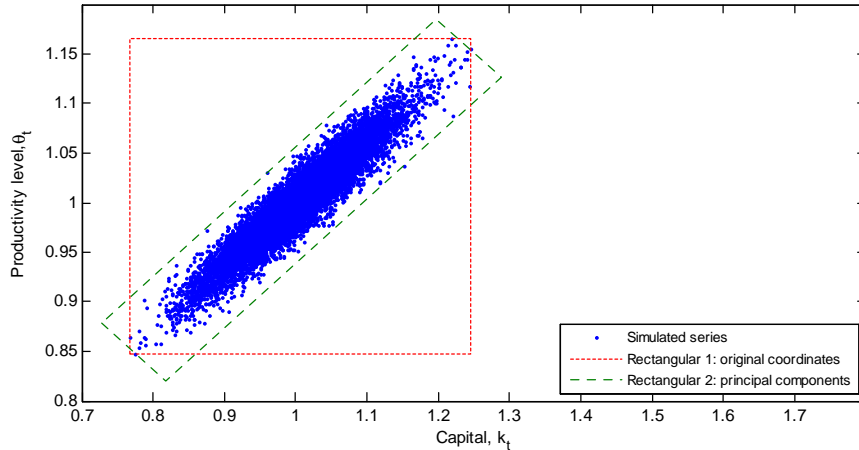

Our example shows that the way in which the rectangular is adapted to the state space of an economic model can matter a lot for the size of the resulting rectangular. How much the rectangular can be reduced by changing the system of coordinates will depend on the shape of the high-probability set. In particular, all rectangulars will have the same size when simulated data are of a shape of a perfect sphere, however, the reduction in size can be fairly large if such the high-probability set is inclined (as is shown in the figure). The reduction in size can be especially large in problems with high dimensionality.

5.2 Smolyak grid on principal components

There are many ways to match a parallelotope into a normalized hypercube in the context of the Smolyak method. We propose an approach that relies on a principle component (PC) transformation and that is convenient to use in economic applications. Namely, we first use simulation to determine the high-probability area of the model's state space (for a sufficiently accurate initial guess), and we then build a parallelotope surrounding the cloud of simulated points.

Let $X \equiv \left(x^1, ..., x^{\mathcal{L}}\right) \in \mathbb{R}^{T \times \mathcal{L}}$ be a set of simulated data, i.e., we have T observations on $\mathcal{L}$ variables. Let the variables $\left(x^1, ..., x^{\mathcal{L}}\right)$ be normalized to zero mean and unit variance. Consider the singular value decomposition of X, defined as $X = USV^\top$, where $U \in \mathbb{R}^{T \times \mathcal{L}}$ and $V \in \mathbb{R}^{\mathcal{L} \times \mathcal{L}}$ are orthogonal matrices, and $S \in \mathbb{R}^{\mathcal{L} \times \mathcal{L}}$ is a diagonal matrix with diagonal entries $s_1 \geq s_2 \geq ... \geq s_{\mathcal{L}} \geq 0$, called *singular values* of X. Perform a linear transformation of X using the matrix of singular vectors V as follows: $Z \equiv XV$, where $Z = \left(z^1, ..., z^{\mathcal{L}}\right) \in \mathbb{R}^{T \times \mathcal{L}}$. The variables $z^1, ..., z^{\mathcal{L}}$ are called *principal components* of X, and are orthogonal (uncorrelated), $\left(z^{\ell'}\right)^\top z^\ell = 0$ for any $\ell' \neq \ell$ and $\left(z^\ell\right)^\top z^\ell = s_\ell^2$. The sample variance of z^ℓ is s_ℓ^2/T, and, thus, z^1 and $z^{\mathcal{L}}$ have the largest and smallest sample variances, respectively.

In Figure 6, we illustrate the four steps of construction of the adaptive parallelotope using PCs.

Figure 6: Smolyak grid on PCs
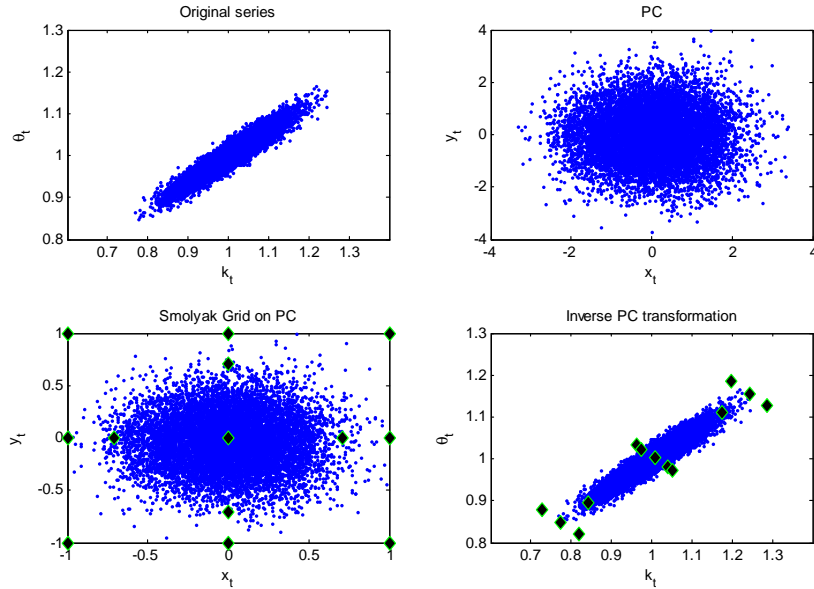

In Panel 1, we show a set of simulated points; in Panel 2, we translate the origin in the center of the cloud, rotate the system of coordinates, renormalize the principal components to have a unit variance in both dimensions and surround it with a hypercube $[-1, 1]^2$. In Panel 3, we show 13 Smolyak points with the approximation level $\mu = 2$ for the principal components of the data. Finally, in Panel 4, we plot the corresponding 13 Smolyak points for the original data

after computing an inverse PC transformation. In Appendix D, we provide additional details on how to construct the rectangular domains for this particular example.

5.3   Advantages of adaptive domain

The size of a parallelotope on which a function is approximated is translated into either higher quality or lower costs of the resulting approximation. For a fixed cost of approximation (i.e., for a given approximation level of the Smolyak method), fitting a polynomial on the relevant domain gives us a better fit inside of such a domain than would give us an otherwise identical method that solves a problem on a large domain and that faces a trade-off between the fit inside and outside the relevant domain. In turn, to attain a given quality of approximation in the relevant domain, we need a more expensive approximation characterized by a higher approximation level if we solve the model on a larger domain than on a smaller domain. Finally, we remark that we can combine asymmetric treatment of variables with an adaptive domain. This could be a potentially useful extension for some applications but we do not pursue it in the present paper.

6   Smolyak method for solving dynamic economic models

The Smolyak method for interpolation is just one specific ingredient of a method for solving dynamic economic models. We need to complement it with other ingredients, such as a procedure for approximation of integrals, a procedure that solves for fixed point coefficients, a procedure that updates the functions along iterations, a procedure that maps the state space of a given economic model into the Smolyak hypercube, etc. In this section, we incorporate the Smolyak method for interpolation into a projection methods for solving dynamic economic models. We assess the performance of the studied Smolyak-based solution method in the context of one- and multi-agent growth models.

6.1   The representative agent model

Our first example is the standard representative agent neoclassical stochastic growth model:

$$\max_{\{c_t, k_{t+1}\}_{t=0}^{\infty}} E_0 \sum_{t=1}^{\infty} \beta^t u(c_t) \tag{38}$$

$$\text{s.t. } c_t + k_{t+1} = (1 - \delta)k_t + \theta_t f(k_t), \tag{39}$$

$$\ln \theta_t = \rho \ln \theta_{t-1} + \sigma \varepsilon_t, \quad \varepsilon_t \sim \mathcal{N}(0, \sigma^2), \tag{40}$$

where $c_t, k_{t+1} \geq 0$, and k_0 and θ_0 are given. Here, c_t and k_t are consumption and capital, respectively; $\beta \in (0, 1)$ is the discount factor; $u(c_t)$ is the utility function, which is assumed to be increasing and concave; $\delta \in (0, 1]$ is the depreciation rate of capital; $f(k_t, \theta_t)$ is the production function with $\alpha \in (0, 1)$ being the capital share in production; and E_t is the operator of expectation conditional on state (k_t, θ_t). The productivity level θ_t in (40) follows a first-order autoregressive process with $\rho \in (-1, 1)$ and $\sigma > 0$.

6.2 Time iteration versus fixed-point iteration

Our implementation of the Smolyak method also differs from the one in Krueger and Kubler (2004) and Malin et al. (2011) in the technique that we use to iterate on decision functions. Specifically, they use time iteration that solves a system of non-linear equations using a numerical solver, whereas we use derivative-free fixed-point iteration that does so using only straightforward calculations. As an illustration, suppose we need to solve a non-linear equation $f(x) = x$; then time iteration finds $\min_x |f(x) - x|$ using a solver, while fixed-point iteration constructs a sequence like $x^{(i+1)} = f(x^{(i)})$, $i = 0, 1, ...$, starting from some initial guess $x^{(0)}$ with the hope that this sequence will converge to a true solution. See Wright and Willams (1984), Miranda and Helmberger (1988), Marcet (1988) for early applications of fixed-point iteration to economic problems. Den Haan (1990) proposed a way to implement fixed-point iteration in models with multiple Euler equations; see also Marcet and Lorenzoni (1999) for related examples. Gaspar and Judd (1997) pointed out that fixed-point iteration is a cheap alternative to time iteration in high-dimensional applications. Finally, Judd et al. (2010, 2011, 2012) show a variant of fixed-point iteration, which performs particularly well in the context of the studied models; we adopt their variant in the present paper. Below, we illustrate the difference between time-iteration and fixed-point iteration methods using the model (38)–(40) as an example.

6.2.1 Time iteration

Time iteration solves a system of three equilibrium conditions with respect to $\widehat{k}'$ in each point of the Smolyak grid. It parameterizes the capital function by Smolyak polynomial $\widehat{k}' = K(k, \theta; b)$, where b is the coefficient vector. It iterates on b by solving for current capital $\widehat{k}'$ given the Smolyak interpolant for future capital $K\left(\widehat{k}', \theta'; b\right)$ (it mimics time iteration in dynamic programming where we solve for the current value function given the future value function):

$$u'(c) = \beta E\left[u'\left(c'_j\right)\left(1 - \delta + \theta'_j \ f'\left(\widehat{k}'\right)\right)\right], \tag{41}$$

$$c = (1 - \delta) k + \theta f(k) - \widehat{k}', \tag{42}$$

$$c'_j = (1 - \delta)\widehat{k}' + \theta'_j f\left(\widehat{k}'\right) - K\left(\widehat{k}', \theta'_j; b\right) b. \tag{43}$$

The system (41)-(43) must be solved with respect to $\widehat{k}'$ using a numerical solver. Observe that Smolyak interpolation $K\left(\widehat{k}', \theta'_j; b\right)$ must be performed for each subiteration on $\widehat{k}'$ using a numerical solver, which is expensive. Time iteration has a high cost even in a simple unidimensional problem.

Time iteration becomes far more expensive in more complex settings. For example, in the multi-agent version of the model, one needs to solve a system of N Euler equations with respect to N unknown capital stocks. A high cost of time iteration procedure accounts for a rapid growth of the cost of the Smolyak method of Malin et al. (2011) with the dimensionality of the problem.

6.2.2 Fixed-point iteration

We also parameterize the capital function using the Smolyak polynomial $\widehat{k}' = K(k, \theta; b)$. Before performing any computation, we rewrite the Euler equation of the problem (38)–(40) in a way, which is convenient for implementing a fixed-point iteration

$$k' = \beta E \left[\frac{u'(c')}{u'(c)} (1 - \delta + \theta' f'(k')) k' \right]. \tag{44}$$

In the true solution, k' on both sides of (44) takes the same values and thus, cancels out. In the fixed-point iterative process, k' on the two sides of (44) takes different values. To proceed, we substitute $k' = \widehat{K}(\cdot; b)$ in the right side of (44), and we get a different value in the left side of (44); we perform iterations until the two sides coincide.[6]

Using parameterization (44), we represent the system of equations (41)-(43) as follows:

$$k' = K(k, \theta; b) \text{ and } k_j'' = K(k', \theta'; b); \tag{45}$$
$$c = (1 - \delta) k + \theta f(k) - k'; \tag{46}$$
$$c' = (1 - \delta) k' + \theta' f(k') - k''; \tag{47}$$
$$\widehat{k}' = \beta E \left[\frac{u'(c')}{u'(c)} (1 - \delta + \theta' f'(k')) k' \right]. \tag{48}$$

In each iteration, given b, we compute k', k'', c, c', substitute them into (48), get $\widehat{k}'$ and continue iterating until convergence is achieved.

In Appendix D, this approach is extended to a multi-agent version of the model to perform iterations on N Euler equations. Even in the multidimensional case, our fixed-point iterative procedure requires only trivial calculations and avoids the need of a numerical solver, unlike the time-iteration method.

Some theoretical arguments suggest that time iteration may possess better convergence properties than fixed-point iteration. In particular, for very simple models, it is possible to show that time iteration has a contraction mapping property locally, which is similar to the one observed for value function iteration; see Judd (1998, p.553) for details. However, the local contraction mapping property is not preserved in more complicated models like the multi-agent model studied later in the paper. It is therefore unknown which iterative scheme has better convergence properties in general. Our simple fixed-point iteration method was reliable and stable in all experiments if appropriate damping is used.

6.3 Algorithm

Below, we show a Smolyak-based projection algorithm for solving the model (38)–(40).

---

[6]This kind of parameterization was used by Den Haan (1990) as a technique to implement the parameterized expectations algorithm in a model with several Euler equations.

Smolyak-based projection method

Initialization.

a. Choose the approximation level, μ.

b. Construct the Smolyak grid $\mathcal{H}^{2,\mu} = \{(x_n, y_n)\}_{n=1,...,M}$ on $[-1,1]^2$.

c. Compute the Smolyak basis functions $\mathcal{P}^{2,\mu}$ in each grid point n.
   The resulting $M \times M$ matrix is $\mathcal{B}$.

d. Fix $\Phi : (k,\theta) \to (x,y)$, where $(k,\theta) \in \mathbb{R}^2_+$ and $(x,y) \in [-1,1]^2$.
   Use Φ^{-1} to compute (k_n, θ_n) that corresponds to (x_n, y_n) in $\mathcal{H}^{2,\mu}$.

e. Choose integration nodes, ϵ_j, and weights, ω_j, $j = 1, ..., J$.

f. Construct future productivities, $\theta'_{n,j} = \theta_n^\rho \exp(\epsilon_j)$ for all j;

g. Choose an initial guess $b^{(1)}$.

Step 1. *Computation of a solution for K.*

a. At iteration i, for $n = 1, ..., M$, compute
   – $k'_n = \mathcal{B}_n b^{(i)}$, where $\mathcal{B}_n$ is the nth row of $\mathcal{B}$.
   – $\left(x'_n, y'_{n,j}\right)$ that corresponds to $\left(k'_n, \theta'_{n,j}\right)$ using Φ.
   – Compute the Smolyak basis functions in each point $\left(x'_n, y'_{n,j}\right)$
   – The resulting $M \times M \times J$ matrix is $\mathcal{B}'$.
   – $k''_{n,j} = \mathcal{B}'_{n,j} b^{(i)}$, where $\mathcal{B}'_{n,j}$ is the nth row of $\mathcal{B}'$ in state j.
   – $c_n = (1 - \delta) k_n + \theta_n f(k_n) - k'_n$;
   – $c'_{n,j} = (1 - \delta) k'_n + \theta_n^\rho \exp(\epsilon_j) f(k'_n) - k''_{n,j}$ for all j;
   – $\widehat{k}'_n \equiv \beta \sum_{j=1}^{J} \omega_j \cdot \left[\frac{u'(c'_{n,j})}{u'(c_n)} \left[1 - \delta + \theta_n^\rho \exp(\epsilon_j) f'(k'_n)\right] k'_n \right]$.

b. Find b that solves the system in Step 1a.
   – Compute $\widehat{b}$ that solves $\widehat{k}' = \mathcal{B}\widehat{b}$, i.e., $\widehat{b} = \mathcal{B}^{-1}\widehat{k}'_n$.
   – Use damping to compute $b^{(i+1)} = (1 - \xi) b^{(i)} + \xi\widehat{b}$, where $\xi \in (0,1]$.
   – Check for convergence: end Step 1 if $\frac{1}{M\xi} \sum_{n=1}^{M} \left| \frac{(k'_n)^{(i+1)} - (k'_n)^{(i)}}{(k'_n)^{(i)}} \right| < 10^{-\vartheta}$, $\vartheta > 0$.

Iterate on Step 1 until convergence.

6.4 Relation to other solution methods in the literature

We now describe the relation between the Smolyak solution method and other numerical methods for solving dynamic economic models in the literature; see Maliar and Maliar (2013) for a survey of numerical methods for solving large-scale dynamic economic models. First, the baseline version of the Smolyak method is similar to conventional projection methods in that it relies on a fixed grid, orthogonal polynomials and deterministic integration methods; see Judd (1992), Gaspar and Judd (1997), Christiano and Fisher (2000), and Aruoba et al. (2006), among others. The difference is that conventional projection methods build on tensor-product rules and their cost grows rapidly with the dimensionality of the problem, whereas the Smolyak method uses non-product rules and its cost grows far more slowly. Second, the anisotropic variant of the Smolyak method is similar to solution methods that use different number of grid points for different variables (e.g., few grid points for shocks and many grid points for capital

as in Aiyagari (1994), Huggett (1993), Rios-Rull (1997), Krusell and Smith (1998)) and other numerical methods that rely on discretization of shocks in line with Tauchen and Hussy (1991). Third, the variant of the Smolyak method with an adaptive domain is related to simulation-based and learning methods; see, e.g., Marcet (1988), Marcet and Sargent (1989), Smith (1991, 1993), Rust (1997), Maliar and Maliar (2005) and Powell (2011). The advantage of simulation-based methods is that they focus on the relevant area of the state space; the shortcoming is that their accuracy is limited by a low rate of convergence of Monte Carlo integration. The Smolyak method with an adaptive domain does not rely on Monte Carlo integration: it uses simulations only for constructing the solution domain, and it uses projection techniques to accurately solve the model on this domain; in this respect, it is similar to combinations of projection and simulation methods studied in Judd (2010, 2011, 2012). Fourth, in contrast to perturbation methods, the Smolyak method is a global solution method whose accuracy does not decline rapidly away from the steady state and that can be used to accurately solve models with strong non-linearities. Fifth, in our examples, we focus on equilibrium problems, however, the techniques described in the paper can be also used in the context of dynamic programming problems. Winschel and Krätzig (2010) show how to use the conventional Smolyak method in the context of canonical value function iteration, however, the Smolyak method can be used in the context of an endogenous grid method of Carroll (2005) and an envelope condition method of Maliar and Maliar (2013a) both of which can significantly reduce the cost of conventional value function iteration. Finally, Brumm and Scheidegger (2013) parallelize a sparse grid method using piecewise local basis functions, and Valero et al. (2013) parallelize a Smolyak method using a global polynomial function; in particular, the latter article also implements parallel computation on a Blacklight supercomputer.

Finally, the anisotropic-grid and adaptive-domain constructions, which we propose in the context of the Smolyak method, will also work for any projection solution method that operates on a hypercube domain including those based on tensor-product rules, e.g., Judd (1992). Also, these construction can be effectively used in the context of low-dimensional problems. However, there are many ways to increase accuracy in problems with low dimensionality, in particular, one can increase the degree of polynomial approximations. In high-dimensional applications, increasing the polynomial degree might be too costly. Anisotropic grids or adaptive domain or their combination may be the only feasible alternative. This is why we advocate these techniques in the context of the Smolyak method applied to problems with high dimensionality.

6.5 Implementation details

Our algorithm builds on techniques that are used in the related literature. To approximate expectation functions, we use a 10-node Gauss-Hermite quadrature rule. We could have used Monte Carlo integration but this would reduce the accuracy dramatically; see Judd et al. (2011) for a discussion.

We consider two mappings $\Phi : X \rightarrow [-1, 1]^2$ that transform each possible value of state variables $(k, \theta) \in X \subseteq \mathbb{R}^2$ into a hypercube (which is a square in the two-dimensional case) $(x, y) \in [-1, 1]^2$. One is a conventional rectangular domain for capital and productivity, and the other is a rectangular domain constructed on principal components of simulated series. The

rectangulars are chosen to enclose the cloud of simulated data as shown in Figure 3. (That is, we solve the model two times: we first compute a solution starting from some initial guess about the ergodic range, we then simulate time series, and we finally recompute solutions more accurately using the rectangular domains that enclose the cloud of simulated data). In Appendix C, we provide further details on the construction of the two mappings.

We use extrema of Chebyshev polynomials as unidimensional grid points, and we use a Chebyshev polynomial family as unidimensional basis functions; in this respect, we are similar to Krueger and Kubler(2004) and Malin et al. (2011). We use the damping parameter $\xi = 0.05$, and we use the convergence criterion $\varpi = 10^{-7}$.

Finally, as a measure of accuracy, we report the mean and maximum of unit-free Euler equation errors on a stochastic simulation of 10,000 observations. Our computer code is written in MATLAB 2012a, and we use a desktop computer with Intel(R) Core(TM) i7-2600 CPU (3.40 GHz) with RAM 12GB. At the initial stage of this project, we benefited from consulting with the Fortran code of Malin et al. (2011).

6.6   Results for the representative agent model

We parameterize the model (38)–(40) by $u(c) = \frac{c^{1-\gamma}-1}{1-\gamma}$, $f(k) = k^{\alpha}$ and $\ln \theta' = \rho \ln \theta + \sigma \varepsilon$, where the parameters are fixed at $\rho = 0.95$, $\beta = 0.99$ and $\alpha = 1/3$. We set the benchmark values of $\delta = 0.025$, $\gamma = 1$ and $\sigma = 0.01$, and we consider variations in γ, σ and δ one-by-one, holding the remaining parameters at the benchmark values. Specifically, we consider

$$
\begin{aligned}
\delta &= \{0,\ 0.1,\ 0.2,\ 0.3,\ 0.4,\ 0.5,\ 0.6,\ 0.7,\ 0.8,\ 0.9,\ 1\}, \\
\gamma &= \{1,\ 5,\ 10,\ 15,\ 20\}, \\
\sigma &= \{0.001,\ 0.005,\ 0.01,\ 0.02,\ 0.03,\ 0.04,\ 0.05\}.
\end{aligned}
$$

We use these parameterizations to test the performance of different versions of the Smolyak method introduced in the paper.

6.6.1   Conventional isotropic Smolyak grids under different approximation levels

We first solve the model (38)–(40) using a baseline version of the Smolyak method under four approximation levels $\mu = 1, 2, 3, 4$. Our baseline version is isotropic, i.e., has the same number of grid points for capital and productivity, and it operates on a rectangular domain in the original system of coordinates. The algorithm was able to converge in a wide range of the parameters and to produce highly accurate solutions.

In Figure 7, we report the (unit-free) maximum residuals in the Euler equation (44) (expressed in log10 units).

The residuals vary from about 1% under $\mu = 1$ to $10^{-8}\%$ under $\mu = 4$. Therefore, the quality of approximation consistently increases with μ.

6.6.2   Anisotropic Smolyak grids

We next consider anisotropic variants of the Smolyak method that use different numbers of grid points for different variables. We consider two possibilities $(\mu_1, \mu_2) = (3, 1)$ and $(\mu_1, \mu_2) = (1, 3)$.

Figure 7: Accuracy of the Smolyak method under different approximation levels.
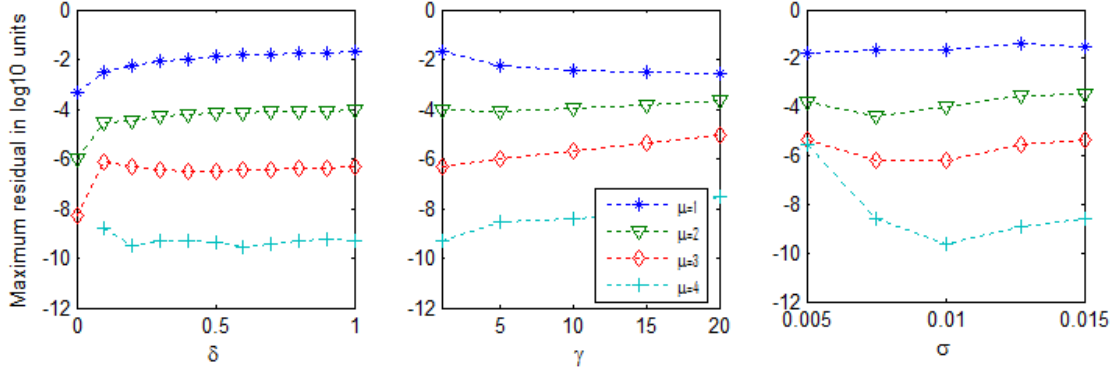

With these constructions, we have 9 elements in the first dimension and 3 elements in the second dimension, which results in 19 elements in total (i.e., 19 grid points and 19 basis functions); these are the elements distinguished in Section 4.2.2.

Figure 8: Accuracy of the Smolyak method with anisotropic grid

In Figure 8, we compare the maximum residuals in the Euler equation with anisotropic grids and isotropic grids. The medium line (the one with triangles) is our benchmark isotropic case $\mu = 2$ that contains 13 polynomial terms.

We observe that if we use more grid points in dimension of capital than in dimension of productivity, the anisotropic Smolyak method produces more accurate solutions than the benchmark isotropic Smolyak method, but if we have more grid points in productivity than in capital, the opposite is true. The difference in accuracy between two anisotropic solutions can be as large as two orders of magnitude. These results illustrate the potential usefulness of anisotropic grids in economic applications.

6.6.3   Adaptive domain

We next assess how the performance of the Smolyak method depends on the choice of the solution domain. We compare the accuracy of solutions of the Smolyak method that operates on the conventional hypercube with that of Smolyak technique that operates on the adaptive

Figure 9: Accuracy of the Smolyak method with adaptive domain
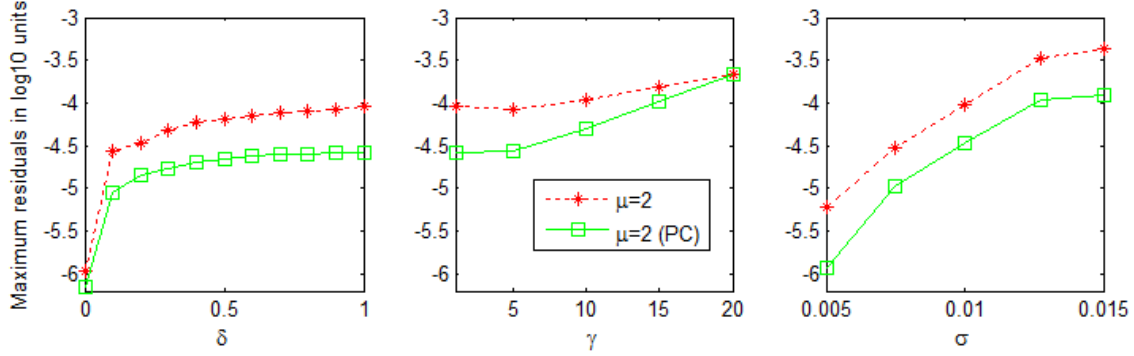

rectangular domain. We compare the maximum residuals in the Euler equation under the conventional and adaptive domains in Figure 9.

The maximum residuals in the Euler equation are about a half order of magnitude (i.e., about 5 times) lower under the adaptive Smolyak domain than under the conventional Smolyak domain for the range of values for γ, σ and δ considered.

6.7   Results for the multicountry model

We now explore the performance of the Smolyak-based projection method in the context of problems with high dimensionality. To this purpose, we extend the one-agent model (38)–(40) to include multiple agents. This is a simple way to expand the size of the problem and to have a control over its dimensionality.

There are N agents, interpreted as countries, that differ in initial capital endowment and productivity level. The countries' productivity levels are affected by both country-specific and worldwide shocks. We study the social planner's problem. If agents are identical in preferences, the planner will allocate identical consumption to all agents. However, we do not make use of the symmetric structure of the economy, and we approximate the planner's solution in the form of N capital policy functions, each of which depends on $2N$ state variables (N capital stocks and N productivity levels). We solve for N policy functions $(k')^h = B^h b^h$, where B^h is a matrix of Smolyak basis functions evaluated in the Smolyak grid points and b^h is a vector of the polynomial coefficients for the countries $h = 1, ...N$. For each country, we use essentially the same computational procedure as the one used for the representative-agent model. The Gauss-Hermite quadrature method builds on product rules and is not tractable in problems with high dimensionality. We replace it with monomial rules combined with Cholesky decomposition; see Judd et al. (2011) for a detailed description of these techniques. For a description of the multicountry model and details of the computational procedure, see Appendix F.

In Figure 10, we compare four different solutions to the multicountry model, namely, the conventional solutions with $\mu = 2$ and $\mu = 3$, the anisotropic solution with $\mu_1^h = 3$ for the capital stocks and $\mu_2^h = 2$ for the productivity levels of all countries, $h = 1, ...N$ (in the figure, we denote this case as $(\mu_1, \mu_2) = (3, 2)$ which means $\left(\mu_1^1, ..., \mu_1^N, \mu_2^1, ..., \mu_2^N\right) = (3, ..., 3, 2, ..., 2)$). Finally, we report the solution with $\mu = 2$ for the Smolyak method with an adaptive domain.

Figure 10: Accuracy and running time for the multicountry model
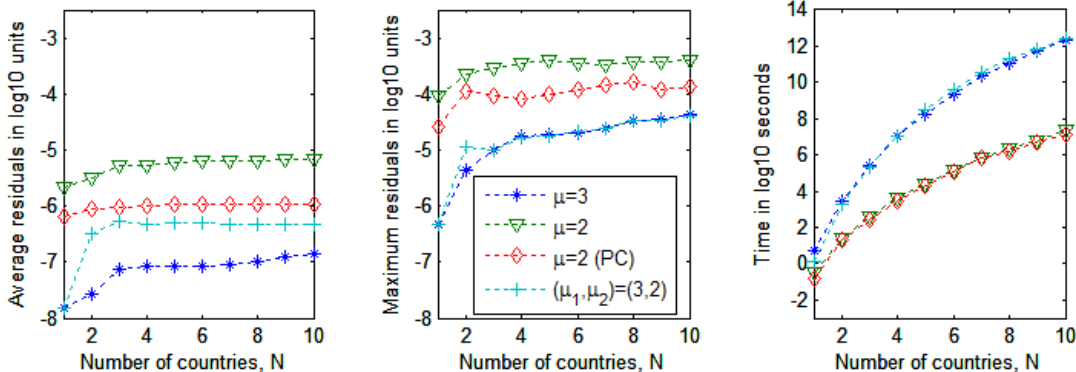

We observe the following results from the figure. First, the difference between the isotropic solution with $\mu = 3$ and that with $\mu = 2$ is about two orders of magnitude. Second, by using an anisotropic grid, we can make half of the way between $\mu = 2$ and $\mu = 3$ in terms of the average residuals, and we obtain essentially identical maximum residuals. Third, the effect of an adaptive domain is also quite sizable, namely, we can reduce the residuals up to one order of magnitude. Finally, we should draw attention to the computational expense of our solution method. We observe a clearly concave pattern for the running time in the logarithmic scale. This means that the expense grows slower than an exponential function, i.e., our implementation does not appear to be subject to the curse of dimensionality in the sense of Bellman (1961).

Malin et al. (2011) also solve models with up to 10 countries (20 state variables); in particular, a symmetric specification of Model I in their analysis is similar to the model studied in the present paper. For this model, their cost in seconds is 1, 59, 916, 7313, 38150 when the number of countries is 2, 4, 6, 8, 10, which grows faster than the exponential function. They use an approximation level $\mu = 2$, and their program is written in Fortran. We differ in two respects: first, we implement the Smolyak method for interpolation by avoiding the repetitions, and second, we use a much cheaper version of fixed-point iteration than time iteration used in Malin et al. (2011). We solve a similar model with 10 countries in about 45 minutes using MATLAB. However, the third-level Smolyak approximation is expensive even for our efficient implementation: we need almost 45 hours to solve a model with 10 countries, which increases accuracy by two orders of magnitude.

Thus, the adaptive domain allows us to make about 1/3 way in terms of accuracy between $\mu = 2$ and $\mu = 3$ without a visible increase in cost. The anisotropic grid with $(\mu_1, \mu_2) = (3, 2)$ gives us essentially the same accuracy as $\mu = 3$ but uses a considerably smaller number of grid points and basis function. However, our current implementation of the anisotropic Smolyak method does not allow us to translate a reduction in the number of Smolyak elements in a sizable cost reduction in this particular example.

35

7   Conclusion

The Smolyak method is designed to deal with high-dimensional applications. However, the cost of the Smolyak method still grows rapidly with dimensionality of the problem. In this paper, we propose a more efficient implementation of the Smolyak method that reduces its computational expense, and we present extensions of the Smolyak method that allow us to increase its accuracy level while maintaining a fixed computational cost. The analytical and numerical techniques developed in the present paper are not limited to economic applications but can be used in other fields.

First, we propose a more efficient implementation of the Smolyak method than the conventional one, namely, we avoid unnecessary repeated evaluations of basis functions when forming the Smolyak interpolant. Efficient implementation of interpolation is especially important in the context of numerical methods for solving dynamic economic models in which decision functions or value function need to be interpolated a very large number of times during the solution procedure, i.e., in each grid point, integration node or time period.

Second, we propose an anisotropic version of the Smolyak grid which allows us to vary the number of grid points and basic functions by dimension. In a typical economic application, we know some properties of decision and value functions, and we may use this knowledge to represent such functions more efficiently using the proposed anisotropic constructions.

Third, we show an effective transformation of the state space of a given economic model into a normalized hypercube used by the Smolyak method. We find that the best accuracy of approximations is attained when we use a minimum hypercube that encloses the high-probability set of a given economic model.

The above three improvements are related to interpolation. Our last improvement is concerned with an iterative procedure for solving dynamic economic models. Time iteration used in the existing Smolyak methods rely on numerical solver while a version of fixed-point iteration used in the present paper involves only straightforward computation. This improvement, although minor in substance, allows us to achieve substantial economizing on cost, especially, in high-dimensional applications.

Appendices

This section contains some supplementary results. In Appendix A, we describe how to construct unidimensional Smolyak grid points and basis functions. In Appendix B, we develop the formula for the Smolyak interpolant in the two-dimensional example with $\mu = 2$. In Appendix C, we show an example of constructing adaptive domain. Finally, in Appendix D, we describe the multicontry model and the solution algorithm.

Appendix A: Unidimensional Smolyak grid points and basis functions

To construct multidimensional Smolyak grid points and basis functions, we must first specify unidimensional grid points and basis functions. Many choice are possible. For example, we can consider a family of ordinary polynomials, $\{1, x, x^2, ...\}$ and grid points generated by dividing the interval $[-1, 1]$ into 2^{i-1} equal parts, $i \geq 2$ (for $i = 1$ we assume a grid point 0). In this manner, for $i = 2$, we have grid points $\{-1, 0, 1\}$ and we have basis functions $\{1, x, x^2\}$; for $i = 3$, we have grid points $\left\{-1, \frac{-1}{2}, 0, \frac{1}{2}, 1\right\}$, and we use basis functions $\{1, x, x^2, x^3, x^4\}$, etc.

Another possibility is to use Chebyshev polynomials as basis functions and extrema of such polynomials as grid points. Approximations based on Chebyshev polynomials have two useful properties. First, there always exists a unique set of coefficients such that a Chebyshev polynomial function matches M given values at M grid points. Second, approximations are uniformly accurate, and error bounds are established. We stick to this choice in our analysis.

Chebyshev polynomials are defined in the interval $[-1, 1]$ with a recursive relation: $T_0(x) = 1$, $T_1(x) = x$, and $T_n(x) = 2xT_{n-1}(x) - T_{n-2}(x)$ for $n \geq 2$.[7] Chebyshev polynomial of degree $n - 1$ has n extrema. Let ζ_j^n be a jth extremum of Chebyshev polynomial of degree $n - 1$ with $j = 1, ..., n$,

$$\zeta_j^n = -\cos\left(\frac{\pi(j-1)}{n-1}\right).$$

Table 6 presents Chebyshev polynomials of degree $n-1$ and their n extrema (for the polynomial of degree 0, the extremum is assumed to be 0). Note that the sequence of unidimensional

Table 6: Extrema of Chebyshev polynomials and construction of Smolyak points in the unidimensional case

n	Chebyshev polynomial of degree $n - 1$ $T_{n-1}(x) = \cos\left((n-1)\cos^{-1}(x)\right)$	n extrema of the polynomial of degree $n - 1$ $\zeta_j^n = -\cos(\frac{\pi(j-1)}{n-1})$, $j = 1, ..., n$
1	1	0
2	x	$-1, \quad 1$
3	$2x^2 - 1$	$-1 \quad 0 \quad 1$
4	$4x^3 - 3x$	$-1, \quad -\frac{1}{2}, \quad \frac{1}{2}, \quad 1$
5	$8x^4 - 8x^2 + 1$	$-1 \quad -\frac{1}{\sqrt{2}} \quad 0 \quad \frac{1}{\sqrt{2}} \quad 1$

Chebyshev polynomials and their extrema cannot be used in Smolyak formula (5) because such sequence does not satisfy Conditions 1 and 2 of Section 2.5, namely, the number of extrema is equal to i, with $i = 1, 2, 3, ...,$ and not to $2^{i-1} + 1$ as required by Condition 1, and the

---

[7]In terms of basis function ψ that was used in the main text and that is used later in Appendix B, we have $T_{n-1}(x) = \psi_n(x)$.

consecutive sets are not nested as required by Condition 2. However, there is a subsequence of this sequence that satisfies both Conditions 1 and 2, and is suitable for the conventional interpolation formula. Namely, we select a subsequence in which the number of extrema is $m(i) = 1, 3, 5, 9, 17, ...$ for $i = 1, 2, 3, 4, 5...$, respectively (the first three sets of such a sequence are in-boxed elements in the last column of the table).

Therefore, the unidimensional Smolyak basis functions and grid points are as follows: for $i = 1$, a grid point is $\{0\}$ and a basis function is $\{1\}$; for $i = 2$, grid points are $\{-1, 0, 1\}$ and basis functions are $\{1, x, 2x^2 - 1\}$; for $i = 3$, grid points are $\left\{\pm 1, \pm \frac{1}{\sqrt{2}}, 0\right\}$ and basis functions are $\{1, x, 2x^2 - 1, 4x^3 - 3x, 8x^4 - 8x^2 + 1\}$; etc.

Appendix B: Smolyak interpolant under $\mu = 2$

We compare two alternative formulas for Smolyak interpolation in the two-dimensional case under the approximation level $\mu = 2$. One is the conventional formula with repeated basis functions and the other is an alternative formula introduced in the present paper.

Conventional Smolyak interpolation formula. We consider the conventional Smolyak formula for interpolation in the two-dimensional case, $d = 2$, under the approximation level $\mu = 2$. Condition $\max(d, \mu + 1) \leq |i| \leq \mu + d$ in (5) becomes $2 \leq i_1 + i_2 \leq 4$. We use (7) to form p^{i_1, i_2}. In particular, $p^{1,1}$, $p^{1,2}$ and $p^{2,1}$ are given by (8)–(10), respectively. For the remaining polynomials, $p^{2,2}$, $p^{3,1}$ and $p^{1,3}$, we have

$$p^{2,2} = \sum_{\ell_1=1}^{m(2)} \sum_{\ell_2=1}^{m(2)} b_{\ell_1 \ell_2} \psi_{\ell_1}(x) \psi_{\ell_2}(y) = b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x)$$
$$+ b_{12}\psi_2(y) + b_{22}\psi_2(x)\psi_2(y) + b_{32}\psi_3(x)\psi_2(y)$$
$$+ b_{13}\psi_3(y) + b_{23}\psi_2(x)\psi_3(y) + b_{33}\psi_3(x)\psi_3(y),$$

$$p^{3,1} = \sum_{\ell_1=1}^{m(3)} \sum_{\ell_2=1}^{m(1)} b_{\ell_1 \ell_2} \psi_{\ell_1}(x) \psi_{\ell_2}(y)$$
$$= b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x) + b_{41}\psi_4(x) + b_{51}\psi_5(x),$$

$$p^{1,3} = \sum_{\ell_1=1}^{m(1)} \sum_{\ell_2=1}^{m(3)} b_{\ell_1 \ell_2} \psi_{\ell_1}(x) \psi_{\ell_2}(y)$$
$$= b_{11} + b_{12}\psi_2(y) + b_{13}\psi_3(y) + b_{14}\psi_4(y) + b_{15}\psi_5(y).$$

Furthermore, $p^{|2|}$ and $p^{|3|}$ are defined before in (11) and (12), respectively. A new combination of polynomials with $|i| = i_1 + i_2 = 4$ is given by

$$p^{|4|} \equiv p^{2,2} + p^{3,1} + p^{1,3}.$$

Smolyak polynomial function (7) for the case $\mu = 2$ is given by

$$\widehat{f}^{2,2}(x,y;b) = \sum_{\max(d,\mu+1)\leq |i|\leq d+\mu} (-1)^{d+\mu-|i|}\binom{d-1}{d+\mu-|i|}p^{|i|}$$

$$= \sum_{3\leq |i|\leq 4} (-1)^{4-|i|}\binom{1}{4-|i|}p^{|i|} = \sum_{3\leq |i|\leq 4} (-1)^{4-|i|}\frac{1}{(4-|i|)!}p^{|i|}$$

$$= -1\cdot p^{|3|} + 1\cdot p^{|4|}$$

$$= -1\cdot (p^{2,1} + p^{1,2}) + 1\cdot (p^{2,2} + p^{3,1} + p^{1,3})$$

$$= b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x) + b_{12}\psi_2(y) + b_{22}\psi_2(x)\psi_2(y)$$

$$+ b_{32}\psi_3(x)\psi_2(y) + b_{13}\psi_3(y) + b_{23}\psi_2(x)\psi_3(y) + b_{33}\psi_3(x)\psi_3(y)$$

$$+ b_{41}\psi_4(x) + b_{51}\psi_5(x) + b_{14}\psi_4(y) + b_{15}\psi_5(y).$$

As expected, the conventional Smolyak formula gives us the same thirteen basis functions as distinguished in (19).

Smolyak interpolation formula without repeated basis functions   Let us now illustrate the use of interpolation formula (25) without repetitions. Here, we have $d \leq |i| \leq \mu + d$, which means $2 \leq i_1 + i_2 \leq 4$. We use formula (27) to form q^{i_1,i_2}. In particular, $q^{1,1}$, $q^{1,2}$ and $q^{2,1}$ are given by (28)–(30), respectively. For the remaining polynomials, $q^{2,2}$, $q^{3,1}$ and $q^{1,3}$, we obtain

$$q^{2,2} = \sum_{\ell_1=m(1)+1}^{m(2)}\sum_{\ell_2=m(1)+1}^{m(2)} b_{\ell_1\ell_2}\psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{22}\psi_2(x)\psi_2(y) + b_{32}\psi_3(x)\psi_2(y)$$

$$+ b_{13}\psi_3(y) + b_{23}\psi_2(x)\psi_3(y) + b_{33}\psi_3(x)\psi_3(y),$$

$$q^{3,1} = \sum_{\ell_1=m(2)+1}^{m(3)}\sum_{\ell_2=m(0)+1}^{m(1)} b_{\ell_1\ell_2}\psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{41}\psi_4(x) + b_{51}\psi_5(x),$$

$$q^{1,3} = \sum_{\ell_1=m(0)+1}^{m(1)}\sum_{\ell_2=m(2)+1}^{m(3)} b_{\ell_1\ell_2}\psi_{\ell_1}(x)\psi_{\ell_2}(y) = b_{14}\psi_4(y) + b_{15}\psi_5(y).$$

Furthermore, $q^{|2|}$ and $q^{|3|}$ are defined before in (31) and (32), respectively. A new sum with $|i| = i_1 + i_2 = 4$ is given by

$$q^{|4|} \equiv q^{2,2} + q^{3,1} + q^{1,3}.$$

The Smolyak polynomial function (27) for the case of $\mu = 2$ is given by

$$\widehat{f}(x,y;b) = \sum_{d\leq |i|\leq d+\mu} q^{|i|} = q^{|2|} + q^{|3|} + q^{|4|}$$

$$= b_{11} + b_{21}\psi_2(x) + b_{31}\psi_3(x) + b_{12}\psi_2(y) + b_{22}\psi_2(x)\psi_2(y)$$

$$+ b_{32}\psi_3(x)\psi_2(y) + b_{13}\psi_3(y) + b_{23}\psi_2(x)\psi_3(y) + b_{33}\psi_3(x)\psi_3(y)$$

$$+ b_{41}\psi_4(x) + b_{51}\psi_5(x) + b_{14}\psi_4(y) + b_{15}\psi_5(y).$$

Again, as expected, our interpolation formula gives the same 13 basis functions as those distinguished in (19) for the conventional Smolyak interpolation formula.

Appendix C: Adaptive domain

We show how to adapt the Smolyak hypercube to the high-probability area of the state space in the context of the representative agent model (38)–(40). Our objective is to define a mapping Φ that transforms each possible value of state variables (k, θ) into $(x, y) \in [-1, 1]^2$. Below, we show two ways of constructing the mapping Φ, one uses the original coordinates and the other uses principal components of the original coordinates.

Standard hypercube. Consider a cloud of simulated data $\{k_t, \theta_t\}_{t=1,\ldots,T}$ shown in Figure 5. Let us define $[\underline{k}, \overline{k}]$ and $[\underline{\theta}, \overline{\theta}]$ as intervals for the state variables that we observe in simulation (the rectangular $[\underline{k}, \overline{k}] \times [\underline{\theta}, \overline{\theta}]$ is the larger rectangular shown in Figure 5. Consider the following linear transformation of $(k, \theta) \in [\underline{k}, \overline{k}] \times [\underline{\theta}, \overline{\theta}]$ into $(x, y) \in [-1, 1]^2$

$$x = 2\frac{k - \underline{k}}{\overline{k} - \underline{k}} - 1 \text{ and } y = 2\frac{\theta - \underline{\theta}}{\overline{\theta} - \underline{\theta}} - 1. \tag{49}$$

By using (49) and its inverse, we can move from $[\underline{k}, \overline{k}] \times [\underline{\theta}, \overline{\theta}]$ to $[-1, 1]^2$. Malin et al. (2011) set bounds exogenously at $[\underline{k}, \overline{k}] = [0.8, 1.2]$ and $[\underline{\theta}, \overline{\theta}] = [\exp(\frac{-0.8\sigma}{1-\rho}), \exp(\frac{0.8\sigma}{1-\rho})]$, where the steady state of both capital and productivity level is one. Our own analysis shows that the best accuracy is attained if the intervals $[\underline{k}, \overline{k}]$ and $[\underline{\theta}, \overline{\theta}]$ are chosen to enclose the set of simulated data as shown in Figure 5.

Adaptive parallelotope. We now describe how to construct the adaptive (inclined) rectangular in Figure 5. To map the state variables into a unit square, we use a principal component (PC) transformation of the time series as described in Section 5 and illustrated in Figure 6. We first normalize the simulated data $\{k_t, \theta_t\}_{t=1,\ldots,T}$ to have zero mean and unit variance by

$$\widetilde{k}_t = \frac{k_t - \mu_k}{\sigma_k} \text{ and } \widetilde{\theta}_t = \frac{\theta_t - \mu_\theta}{\sigma_\theta}, \tag{50}$$

where μ_k and μ_θ are means, and σ_k and σ_θ are standard deviations of of capital and shock, respectively. We then compute the SVD decomposition $Y = USV^\top$, where $Y \equiv \begin{bmatrix} \widetilde{k}_1 & \widetilde{\theta}_1 \\ \vdots & \vdots \\ \widetilde{k}_T & \widetilde{\theta}_T \end{bmatrix}$, $U \in \mathbb{R}^{T \times 2}$ and $V \in \mathbb{R}^{2 \times 2}$ are orthogonal matrices, and $S \in \mathbb{R}^{2 \times 2}$ is a diagonal matrix of singular values. We find $Z \equiv YV$, where $Z = \begin{bmatrix} z_1^x & z_1^y \\ \vdots & \vdots \\ z_T^x & z_T^y \end{bmatrix} \in \mathbb{R}^{T \times 2}$. Let $[\underline{z}^x, \overline{z}^x]$ and $[\underline{z}^y, \overline{z}^y]$

be the intervals for the resulting principal components $\{z_t^x, z_t^y\}_{t=1,\ldots,T}$. We map each $(z^x, z^y) \in [\underline{z}^x, \overline{z}^x] \times [\underline{z}^y, \overline{z}^y]$ into $(x, y) \in [-1, 1]^2$ using

$$x = 2\frac{z^x - \underline{z}^x}{\overline{z}^x - \underline{z}^x} - 1 \text{ and } y = 2\frac{z^y - \underline{z}^y}{\overline{z}^y - \underline{z}^y} - 1. \tag{51}$$

To go back to the state space of the model, we first find (z^x, z^y) that correspond to a given pair (x, y) using (51), we then apply an inverse PC transformation to get $\left(\widetilde{k}, \widetilde{\theta}\right)^\top = V^{-1} (z^x, z^y)^\top$ and finally, we compute (k, θ) using the inverse of (50).

In our experiments, we typically recompute solutions two times: First, we solve the model using the standard rectangular domain in the original system of coordinates for some guess $\left[\underline{k}, \overline{k}\right] \times \left[\underline{\theta}, \overline{\theta}\right]$. After the decision functions were computed, we simulate the model and use the time series solution $\{k_t, \theta_t\}_{t=1,\ldots,T}$ either to refine the guess on the bounds $\underline{k}$, $\overline{k}$, $\underline{\theta}$ and $\overline{\theta}$ for constructing the conventional domain or to compute μ_k, μ_θ, σ_k, σ_θ, V, $\underline{z}^x$, $\overline{z}^x$, $\underline{z}^y$ and $\overline{z}^y$ for constructing the adaptive domain.

Appendix D: Smolyak-based projection methods for problems with high dimensionality

We describe the multicountry model studied in Section 6.7 and provide further computational details about the Smolyak method that was used to produce numerical solutions in that section.

Appendix D1. Multicountry model

We test the performance of the Smolyak-based projection method in the context of the multi-agent model studied in Judd (2010, 2011, 2012). This allows us to compare the performance of the Smolyak method with other approaches tractable in high-dimensional applications.

A world economy consists of a finite number of agents N, interpreted as countries. Each country $h \in \{1, \ldots, N\}$ is populated by a representative consumer. A social planner solves the following maximization problem:

$$\max_{\left\{c_t^h, k_{t+1}^h\right\}_{t=0,\ldots,\infty}^{h=1,\ldots,N}} E_0 \sum_{h=1}^{N} \lambda^h \left[\sum_{t=0}^{\infty} \beta^t u^h \left(c_t^h\right)\right] \tag{52}$$

subject to the aggregate resource constraint,

$$\sum_{h=1}^{N} c_t^h + \sum_{h=1}^{N} k_{t+1}^h = \sum_{h=1}^{N} k_t^h (1 - \delta) + \sum_{h=1}^{N} \theta_t^h A f^h \left(k_t^h\right), \tag{53}$$

and to the process for the countries' productivity levels,

$$\ln \theta_{t+1}^h = \rho \ln \theta_t^h + \epsilon_{t+1}^h, \qquad h = 1, \ldots, N, \tag{54}$$

44

where initial condition $\left\{k_0^h, \theta_0^h\right\}^{h=1,...,N}$ is exogenously given, and the productivity shocks follow a multivariate Normal distribution $\left(\epsilon_{t+1}^1, ..., \epsilon_{t+1}^N\right)^{\top} \sim \mathcal{N}\left(0_N, \Sigma\right)$ with $0_N \in \mathbb{R}^N$ being a vector of zero means and $\Sigma \in \mathbb{R}^{N \times N}$ being a variance-covariance matrix. We assume that shocks of different countries are given by $\epsilon_{t+1}^h = \varsigma_t^h + \varsigma_t$, $h = 1, ..., N$, where $\varsigma_t^h \sim \mathcal{N}\left(0, \sigma^2\right)$ is a country-specific component, and $\varsigma_t \sim \mathcal{N}\left(0, \sigma^2\right)$ is a worldwide component. The resulting variance covariance matrix is $\Sigma = \begin{pmatrix} 2\sigma^2 & ... & \sigma^2 \\ ... & ... & ... \\ \sigma^2 & ... & 2\sigma^2 \end{pmatrix}$.

In the problem (52)–(54), E_t is the operator of conditional expectation; c_t^h, k_t^h, θ_t^h and λ^h are a country's h consumption, capital, productivity level and welfare weight, respectively; $\beta \in (0, 1)$ is the discount factor; $\delta \in (0, 1]$ is the depreciation rate; A is a normalizing constant in the production function; $\rho \in (-1, 1)$ is the autocorrelation coefficient. The utility and production functions, u^h and f^h, respectively, are strictly increasing, continuously differentiable and concave. We assume that all countries have identical preferences and technology, i.e. $u^h = u$ and $f^h = f$ for all h. Under these assumptions, the planner assigns equal weights, $\lambda^h = 1$, and therefore, equal consumption to all countries, $c_t^h = c_t$ for all $h = 1, .., N$.

Appendix D2. Algorithm for the multicountry model

The solution to the model (52)–(54) satisfies N Euler equations:

$$k_{t+1}^h = E_t\left\{\beta\frac{u'\left(c_{t+1}\right)}{u'\left(c_t\right)}\left[1 - \delta + \theta_{t+1}^h Af'\left(k_{t+1}^h\right)\right]k_{t+1}^h\right\}, \quad h = 1, ..., N, \tag{55}$$

where u' and f' are the first derivatives of u and f, respectively.

We approximate the planner's solution as N capital policy functions $K^h\left(\left\{k_t^h, \theta_t^h\right\}^{h=1,...,N}\right)$. Note that our approximating functions $\widehat{K}^h\left(\left\{k_t^h, \theta_t^h\right\}^{h=1,...,N}; b^h\right)$, $h = 1, ..., N$, are country-specific. In effect, we treat countries as completely heterogeneous even if they are identical in fundamentals and have identical optimal policy functions. This allows us to assess costs associated with computing solutions to models with heterogeneous preferences and technology.

Steps of the Smolyak-based projection method. The Smolyak method, described for the representative agent model in the main text, can be readily extended to the multicountry case.

- *Initialization:*

  (a) Choose the level of approximation, μ.

  (b) Parameterize $\left(k^h\right)' = K^h\left(\left\{k_t^h, \theta_t^h\right\}^{h=1,...,N}\right)$ with $\widehat{K}^h\left(\left\{k_t^h, \theta_t^h\right\}^{h=1,...,N}; b^h\right)$ which is a Smolyak interpolant constructed using Chebyshev unidimensional basis functions.

  (c) Construct a Smolyak grid $\mathcal{H}^{2N,\mu} = \left\{x_n^h, y_n^h\right\}_{n=1,...,M}^{h=1,...,N}$ on the hypercube $[-1, 1]^{2N}$, as described in Section 3 and 4 for isotropic and anisotropic cases, respectively.

(d) Compute Smolyak basis functions $\mathcal{P}^{2N,\mu}$ in each grid point n as described in Section 3 for the isotropic case or in Section 4 for the anisotropic case. The resulting $M \times M$ matrix is $\mathcal{B}$.

(e) Choose the relevant ranges of values for $\left\{ k_t^h, \theta_t^h \right\}^{h=1,...,N}$ on which a solution is computed. The resulting hypercube is $\left[\underline{k}^1, \overline{k}^1 \right] \times ... \times \left[\underline{\theta}^N, \overline{\theta}^N \right]$.

(f) Construct a mapping between points $\left\{ k_n^h, \theta_n^h \right\}^{h=1,...,N}$ in the original hypercube $\left[\underline{k}^1, \overline{k}^1 \right] \times ... \times \left[\underline{\theta}^N, \overline{\theta}^N \right]$ and points $\left\{ x_n^h, y_n^h \right\}^{h=1,...,N}$ in the normalized hypercube $[-1,1]^{2N}$ using either a linear change of variables of type (49) or principal component transformation of type (51); see Section 5.

$$\Phi : \left[\underline{k}^1, \overline{k}^1 \right] \times ... \times \left[\underline{\theta}^N, \overline{\theta}^N \right] \to [-1, 1]^{2N} . \tag{56}$$

(g) Choose integration nodes, $\left\{ \epsilon_j^h \right\}^{h=1,...,N}$, and weights, ω_j, $j = 1, ..., J$.

(h) Construct next-period productivity, $\left\{ \left(\theta_{n,j}^h \right)' \right\}^{h=1,...,N}$ with $\left(\theta_{n,j}^h \right)' = \left(\theta_n^h \right)^\rho \exp \left(\epsilon_j^h \right)$ for all j and n.

(k) Make an initial guess on the coefficients vectors $(b^1)^{(1)}, ..., (b^N)^{(1)}$.

• *Iterative cycle. At iteration i, given $(b^1)^{(i)}, ..., (b^N)^{(i)}$, perform the following steps.*

• Step 1. *Computation of the capital choice.*
Compute $(k_n^h)' = \mathcal{B}_n (b^h)^{(i)}$, where $\mathcal{B}_n$ is the nth row of $\mathcal{B}$ for $n = 1, ..., M$.

• Step 2. *Computation of the consumption choice.*
Compute $\left\{ c_n^h \right\}^{h=1,...,N}$ satisfying (53) given $\left\{ k_n^h, \theta_n^h, (k_n^h)' \right\}^{h=1,...,N}$ for $n = 1, ..., M$.

• Step 3. *Approximation of conditional expectation.*
For $n = 1, ..., M$,

(a) compute:
- $\left\{ \left(x_{n,j}^h \right)', \left(y_{n,j}^h \right)' \right\}^{h=1,...,N}$ that correspond to $\left\{ \left(k_n^h \right)', \left(\theta_{n,j}^h \right)' \right\}^{h=1,...,N}$ using the inverse of transformation (56);
- Smolyak basis functions $\mathcal{P}^{2N,\mu}$ in each point $\left\{ \left(x_{n,j}^h \right)', \left(y_{n,j}^h \right)' \right\}^{h=1,...,N}$; the resulting $M \times M \times J$ matrix is $\mathcal{B}'_{n,j}$;
- $\left(k_{n,j}^h \right)'' = \mathcal{B}'_{n,j} (b^h)^{(i)}$, where $\mathcal{B}'_{n,j}$ are basis functions evaluated in $\left\{ \left(k_n^h \right)', \left(\theta_{n,j}^h \right)' \right\}^{h=1,...,N}$ using the transformation (56) for all j;
- $\left\{ \left(c_{n,j}^h \right)' \right\}^{h=1,...,N}$ satisfying (53) given $\left\{ \left(k_n^h \right)', \left(\theta_{n,j}^h \right)', \left(k_{n,j}^h \right)'' \right\}^{h=1,...,N}$ for $n = 1, ..., M$;

(b) evaluate conditional expectation:

$$e_n^h \equiv \beta \sum_{j=1}^{J} \left\{ \omega_j \left(\frac{u_1^h \left(\left(c_{n,j}^h \right)' \right)}{u1 \left(c_n^h \right)} \left[1 - \delta + \left(\theta_{n,j}^h \right)' f_1^h \left(\left(k_n^h \right)' \right) \right] \left(k_n^h \right)' \right) \right\}.$$

- Step 4. *Computation of the coefficients.*
  Find $\left\{ \widehat{b}^h \right\}^{h=1,...,N}$ that solves $e_n^h = \mathcal{B}_n \widehat{b}^h$, i.e., $\widehat{b}^h = \mathcal{B}_n^{-1} e_n^h$.

- Step 5. *Updating of the coefficients vectors.*
  For each $h = 1, ..., N$, compute the coefficients vector for the subsequent iteration $i + 1$ using fixed-point iteration,

$$\left(b^h \right)^{(i+1)} = (1 - \xi) \left(b^h \right)^{(i)} + \xi \widehat{b}^h. \tag{57}$$

where $\xi \in (0,1)$ is a damping parameter.

Iterate on Steps 1–5 until convergence of the solution,

$$\frac{1}{MN\xi} \sum_{n=1}^{M} \sum_{h=1}^{N} \left| \frac{\left(\left(k_n^h \right)' \right)^{(i+1)} - \left(\left(k_n^h \right)' \right)^{(i)}}{\left(\left(k_n^h \right)' \right)^{(i)}} \right| < 10^{-\vartheta}, \tag{58}$$

where $\left(\left(k_n^h \right)' \right)^{(i+1)}$ and $\left(\left(k_n^h \right)' \right)^{(i)}$ are the hth country's capital choices on the grid obtained on iterations $i + 1$ and i, respectively, and $\vartheta > 0$.

Computational details. To solve the model, we assume $u(c_t) = \frac{c_t^{1-\gamma}-1}{1-\gamma}$, $f(k_t) = k_t^{\alpha}$ with $\alpha = 0.36$, $\beta = 0.99$, $\rho = 0.95$ and we vary γ, δ and σ. We start iterations from an arbitrary initial guess on the capital decision function, $k_{t+1}^h = 0.9k_t^h + 0.1\theta_t^h$ for all $h = 1, ...N$ (this guess matches the steady-state level of capital). To approximate integrals, we use a monomial integration rule with $2N$ nodes combined with Cholesky decomposition; see Judd et al. (2011) for a description of these techniques. We set the damping parameter in (57) at $\xi = 0.05$, and we set the tolerance parameter in convergence criterion (58) at $\vartheta = 7$.
