Central Bank Swap Arrangements in the COVID-19 Crisis
Joshua Aizenman, Hiro Ito, and Gurnain Kaur Pasricha
NBER Working Paper No. 28585
March 2021
JEL No. F15,F21,F32,F36,G15

ABSTRACT

Facing acute strains in the offshore dollar funding markets during the COVID-19 crisis, the Federal Reserve (Fed) implemented measures to provide US dollar liquidity by reinforcing swap arrangements with five major central banks, reactivating them with nine other central banks and establishing a financial institutions and monetary authorities (FIMA) repo facility in March 2020. This paper assesses motivations for the Fed liquidity lines, and the effects and spillovers of US dollar auctions by central banks, for about 50 economies. We find that the access to the liquidity arrangements is driven by the recipient economies' close trade ties with the US. Higher US bank and trade exposure to an economy increases its access to dollar liquidity lines through the swap arrangements and the new repo facility. Access to dollar liquidity also reflects global trade exposure. We investigate the announcement effects of the liquidity arrangements on several key financial variables, and find that announcements of expansion of Fed liquidity facilities led to appreciation of partner currencies against the US dollar, improved CDS spreads, and lowered the long-term interest rates of the recipient economies. Further, US dollar auctions by economies' own central banks lead to temporary appreciation of their currencies, but dollar auctions by major central banks (BoE, ECB, BoJ and SNB) have persistent spillovers – they led to appreciation of other non-dollar currencies. These responses do not differ whether the economies have larger or smaller financial or trade ties with the US.

1. Introduction

Facing acute strains in the offshore dollar funding markets during the COVID-19 crisis (Figure 1), the US Federal Reserve (Fed) took several actions to provide US dollar liquidity through foreign central banks. It reduced the pricing of swap operations, extended the maturity, and increased the frequency of swap operations with the major central banks with which it has standing swap lines: the Bank of Canada (BOC), the Bank of England (BOE), the Bank of Japan (BOJ), the European Central Bank (ECB), and the Swiss National Bank (SNB). On March 19, 2020, the Fed reactivated the swap lines it had established with nine central banks at the time of the Global Financial Crisis (GFC) of 2008 and doubled their maximal lines (Table 1).¹

Furthermore, for the first time, on March 31, 2020, the Fed announced the establishment of a temporary repurchase agreement facility for foreign and international monetary authorities (aka FIMA) repo facility. With this facility, the Fed could enter into repo agreements with foreign central banks and international institutions, and supply US dollar liquidity in exchange for existing US Treasuries held by these institutions. The FIMA facility was expected to reduce the need for the sale of US Treasuries and mitigate pressure in this market.

FIMA facility has ambivalent characteristics from the perspective of other economies. On the one hand, it is egalitarian because the facility is accessible not only to economies with standing swap lines or bilateral repo arrangements with the Fed, but also to economies which do not have any such agreements, or whose banks do not have direct access to the Fed's lending window through their US subsidiaries or branches. On the other hand, however, liquidity through FIMA is not equally accessible. It is more easily available for those economies which already hold a large volume of US Treasuries. The pricing of this line is also more expensive than that of bilateral arrangements.

US dollar liquidity was actively provided to local markets through US dollar auctions by many central banks: first in mid- to late-March, 2020 by the four major central banks, ECB, BOJ,

¹ They are: the Reserve Bank of Australia (RBA), the Banco Central do Brasil (BCB), the Bank of Korea (BoK), the Banco de Mexico (BdM), the Monetary Authority of Singapore (MAS), the Sveriges Riksbank (Sweden, SR) with the maximal lines of \$60 billion; and the Danmarks Nationalbank (DNB), the Norges Bank (Norway, NB), and the Reserve Bank of New Zealand (RBNZ) with the maximal lines of \$60 billion.

SNB, and BOE, then by 12 other central banks (Figure 2). The US dollar auctions by the major central banks used US dollars obtained via swap lines with the Fed and were larger in magnitude than the US dollar auctions by other central banks. The auctions by the other 12 central banks that published data on these auctions, used either US dollars obtained via swap lines with the Fed or their own foreign exchange reserves. In the case of Hong Kong, the US dollars were obtained via the FIMA facility.² The US dollar shortage was mitigated by late June, so was the demand for US dollar liquidity from major central banks (Figure 3).

Research on the extension of swap lines during the GFC suggests that US bank exposure to the swap partner economies and the extent of reliance on the US as their export destination are important motivations for the Fed to extend these lines (Aizenman and Pasricha, 2010; Aizenman, Jinjarak, and Park, 2011).

Given that the economic environment in the COVID turmoil was different from that of the GFC, which was a shock that originated in the US financial system, and that FIMA facility was added as another liquidity provision scheme, one may ask whether the factors motivating the US decision to provide dollar liquidity were different in this crisis. Did the Fed extend swap lines or FIMA facility solely based on its self-interest as it did during the GFC? What factors determined economies' access to dollar liquidity? One may also ask to what extent the size of US dollar auctions conducted by central banks reflected stress in domestic financial or currency markets.

Other questions are also worth investigating. Are the swap lines effective in mitigating financial stress? The announcements of swap lines during the GFC had relatively large short-run impacts on the exchange rates of the selected emerging market economics (EMs), but much smaller effect on the credit default swap (CDS) spreads, relative to that of other EMs that were not the recipients of swap-lines (Aizenman Pasricha, 2010). Baba and Packer (2009) found that US dollar term funding auctions by the ECB, SNB, and BoE, as well as the Fed's commitment to provide unlimited dollar swap lines ameliorated the FX swap market dislocations during the GFC. Rose and Spiegel (2012) found that US dollar auctions by major central banks

² The Hong Kong Monetary Authority announced on April 22, 2020, the launch of a US dollar liquidity facility based on US dollars obtained via FIMA. In addition, central banks of Colombia and Chile announced on April 20, 2020 and June 24, 2020 respectively, that they had gained access to FIMA.

disproportionately benefitted economies that had higher trade or asset exposure to the US, by reducing their CDS spreads.

We revisit these questions and investigate whether the announcement of the dollar liquidity lines by the Fed as well as that of dollar auctions by central banks affect the performance of their exchange rates, cross-currency basis (CIP deviations), CDS spreads, and government bond yields. We distinguish between dollar auctions by an economy's own central bank and those by the five major central banks, and ask whether the impacts were different, and whether the auctions by the major central banks had spillovers on the financial conditions in other economies. We use a local projection model and daily data from 1 January 2020 to 31 May 2020, on a sample of 45 economies to investigate these questions about the impact of liquidity facilities.

Our results indicate that an economy's share in US trade and a military alliance with the US are the positive factors that determined access to a Fed swap agreement. On the determinants of the size of access to liquidity arrangements, we find that an economy with high levels of US bank exposure and stronger trade ties with the US tended to have greater access to Fed liquidity, via swap lines or FIMA. Economies with a large share of global trade, regardless of whether they are major trading partners of the US, also had greater access to US dollar liquidity via the Fed.

The access to US dollar liquidity lines was largely determined by pre-existing characteristics of the economies. However, the demand for US dollars auctioned by central banks should reflect the ongoing stressed in the domestic currency and financial markets. We find that economies that faced appreciation pressures against the US dollar and whose local currency exchange rate becomes more volatile were more likely to auction greater amounts of US dollars in its domestic market. While this may sound paradoxical, the record of the GFC is that from gold to the US dollar to the Japanese yen, 'safe havens' were greatly sought – and greatly affected – by investors reacting to the global financial crisis. Thereby, the appreciation and the volatility of the yen are intertwined with the collapsing export/GDP of Japan during that time.

As for the announcement effects of the swap lines and dollar auctions by central banks, we find that the announcement of expansionary changes in the swap arrangements and the creation of the FIMA facility led to appreciation of non-US dollar currencies against the US dollar, as expected. While the swap or FIMA announcements had no impact on cross-currency basis, they improved (i.e., reduced) CDS spreads and lowered the 10-year government bond yields. Dollar

auctions by central banks led to temporary appreciation of their currencies, but dollar auctions by major central banks (BoE, ECB, BoJ and SNB) had persistent spillover effects – they led to appreciation of other, non-major currencies against the US dollar.

Putting our results in the proper context, the conceptual differences between international reserves and emergency swap lines and emergency liquidity arrangements are noteworthy. The demand for international reserves is shaped by precautionary motives, i.e., ex ante insurance against future sudden stops and trade funding challenges; and possibly concerns about trade competitiveness, dubbed sometimes as mercantilist motives (Aizenman, 2008). In contrast, emergency liquidity arrangements and swap lines provided during the GFC and the COVID-19 crisis provide liquidity relief at the time of crisis. Hence, there is no presumption that the demand for international reserves are explained by the same factors determining emergency liquidity and swap lines. At times of financial crisis, trade credits supplied by local banks may shrink even in economies experiencing currency appreciation, as banks may opt to reduce their risk exposure, documented by Amiti and Weinstein (2011).³ During a deep crisis with uncertain duration, like the GFC, economies may use their international reserves as a first line of defense, but may refrain from tapping too deeply to reserves out of the fear that depleting reserves may cost them dearly if the crisis would deepen in the future (Aizenman and Sun, 2012). In these

³ The appreciation the yen in 2008 coincided with collapsing trade credit in Japan, magnifying the contraction of international trade at times that ‘flight to safety’ induced yen appreciation. Amiti and Weinstein (2011) identify the presence of a causal link from shocks in the financial sector to exporters that result in exports declining much faster than output during banking crises. They concluded that the health of financial institutions is an important determinant of firm-level exports during crises. Since the evidence indicates that exporters in many countries are highly dependent on trade finance, these results imply that financial shocks are likely to play important roles in export declines in other countries as well. Thereby, financial and trade shocks are intertwined in different ways across countries during crises. This pattern is in line with IMF-BAFT Survey (2009), reported by Amiti and Weinstein (2009), of 88 banks in 44 countries revealed that the average spreads on the letters of credit, export credit insurance, and short- to medium-term trade-related lending rose by 70, 107, and 99 basis points, respectively, in the second quarter of 2009 relative to the fourth quarter of 2007. See also Auboin (2009) review on trade credits before and during the GFC, noting that ‘While a number of public-institutions mobilized financial resources for trade finance in the fall of 2008, this has not been enough to bridge the gap between supply and demand of trade finance worldwide. As the market situation continued to deteriorate in the first quarter of 2009, G-20 leaders in London (April 2009) adopted a wider package for injecting additional liquidity and bringing public guarantees in support of \$250 billion of trade transactions in 2009 and 2010.’

circumstances, swap lines and FIMA type of arrangements may mitigate the decline of trade credit, the depletion rate of international reserves, and mitigate the rise of sovereign spreads of exposed emerging markets.⁴

Boissay, Patel and Shin (2020) indicate that the forces of these factors have only increased after the GFC due to the dominant role of dollar funding, and the growing depth of the global supply chains. Specifically, they noted:

“Trade finance, as proxied by the share of cross-border factoring in total factoring, has steadily increased over the past two decades. This long-term trend has gone hand in hand with the rise in international trade and, more specifically, the lengthening of global value chains (GVCs). While the lengths of domestic production chains estimated using world input-output tables at the country-sector level have remained constant, GVCs involving multiple border crossings have lengthened significantly between 2000 and 2017. Since financing needs increase with the length of supply chains (Bruno et al (2018), Bruno and Shin (2019)), trade finance has become more prominent in the context of GVCs.” (page 5). “The sharp appreciation of the dollar in the early stages of the Covid-19 crisis may have had knock-on effects to trade finance from stress in the banking system. Given the prevalence of the US dollar in trade financing, mitigating the impact of dollar credit fluctuations will be an important component of shielding global value chains from the pandemic’s economic fallout. In this respect, the recent expansion of central bank dollar swap lines and other measures to mitigate dollar liquidity conditions are likely to further cushion trade finance.” (page 6).

Baldwin and Freeman (2020) also highlight the magnification of the intermingling of trade and finance associated with the of the GVC deepening. The COVID pandemic vividly illustrated the dependence of the US and the EU on the GVC as the source of critical medical supplies. These considerations imply that we should take the econometric significance of the ‘trade factors’ in our regressions with a grain of salt: one needs micro data to identify more sharply the role of trade, finance and the interaction between the two.

The results of our paper also are in line with Gourinchas and Rey (2007), Obstfeld et al. (2009), and Gopinath et al. (2020), analyzing the “exorbitant privilege” position of the US dollar, and the dominant currency paradigm. These considerations suggest that the FEDs swap lines and emergency liquidity provisions of the FIMA type may impact most emerging and developing

⁴ If the economy of concern is long in dollar assets (e.g., Japan, Germany, Switzerland), its currency’s appreciation would induce valuation losses in terms of its domestic currency (in addition to adverse impacts on international trade), magnifying the losses on the US equities and putting more pressure on the economy’s balance sheet. Hence, even with its currency appreciation, financial instability may arise.

economies, including nations with limited trade and financial dealings with the US. For economies with greater trade and financial integration with the US, these effects tend to be more direct, for others, in the form of spillovers.

The paper is organized as follows. In Section 2, we first reexamine what factors led the Fed to select nine countries as swap partner countries as it did during the GFC. We then investigate the determinants of the size of liquidity lines – both swap and FIMA- in Section 3. In Section 4, we examine the determinants of the size of dollar auctions by central banks. In Section 5, we examine the impact of the liquidity lines and dollar auctions by central banks on important financial variables. In Section 6, we present the results of numerous robustness checks. In Section 7, we make concluding remarks.

2. *Probability of gaining access to Fed swap lines*

The COVID-19 crisis saw a re-emergence of dollar liquidity shortages around the world, as evidenced by the widening of the cross-currency basis between the US dollar and other currencies (Figure 1). While the Fed reactivated swap lines with the same nine central banks with which it had established them in 2008. However, considering the difference in the economic conditions between the GFC and the COVID crisis as well as the difference in terms of the type of shock that hit the world economy (i.e., financial crisis originating in the US vs. the pandemic), the determinants for the selection of the nine central banks may differ between the two crisis episodes.

Hence, it is worthwhile to examine what factors led the nine central banks to be selected to receive swap liquidity lines from the Fed again. Following Aizenman and Pasricha (2010), we estimate the factors that affect the probability of economies included in the swap agreements. The candidate factors are: exposure of US banks to individual economies (*BankExp*), measured by the share of the individual market in the consolidated foreign claims of US banks; trade exposure to the US (*TradeShare*), measured by the share of economy *i* in total US goods imports and exports; financial openness (*KAOPEN*) measured by the Chinn-Ito index of capital account openness (2006, 2008); and the existence of formal military relationship with the US (*ALLIANCE*).

By extending US dollar liquidity to economies where US banks have greater asset exposure, the Fed could prevent costly deleveraging, possibly enhancing the welfare of both - source and recipient - economies. The more trade economy i conducts with the US, the greater the incentive of the Fed to secure trade flow by readily granting liquidity lines to the economy. A more financially open economy might have more need of liquidity lines, as the size of financial shock it faces may be larger due to its greater integration with global financial system. A non-economic factor may matter: the US may prefer providing swap lines with economies it has closer geopolitical relationship.

We apply the probit estimation model to a sample of 63 economies. This sample does not include Canada, the euro countries, Japan, Switzerland, and the United Kingdom because these countries have standing swap lines with the Fed. The dependent variable is a dummy variable that takes the value of unity when the economy of concern is selected as the recipient of swap lines. All the explanatory variables are sampled as of the end of 2019.

Columns of (1) through (4) of Table 2 show that all the candidate variables are significant contributors to selection into Fed's swap agreements when they are included alone. Greater US banks' exposure, greater US trade exposure, more open financial markets, and the existence of military alliance increase the probability of receiving a Fed swap line. Among the three variables, the dummy for a military relationship with the US alone explains the probability of providing a swap line the most (pseudo R^2 of 24%).

Columns (5) through (7) include the dummy for military alliance and two of the remaining three variables. Among the three models, the model in column (6), with US trade exposure and de-jure financial openness of the economy, yields the highest pseudo R^2 , though the estimate on financial openness becomes statistically insignificant. When we include all the candidate variables in the estimation, the variables for the share in US trade and military alliance maintain statistical significance. Financial exposure may contribute positively to the probability of selection for the swap arrangement, but its contribution is not as significant as that of US trade exposure.

If we interpret a predicted probability of selection of 15% or more as a selection prediction, models (5), (6), and (8) correctly predict 8 out of 9 swap arrangements and 42 or 43 out of 53

cases where such arrangements were not made.⁵ The impacts of trade exposure and military alliance are not only econometrically significant but also economically significant. If the level of trade exposure rises by one standard deviation, the probability of getting selected for the swap arrangement would go up by 5.3 percentage points. When all the explanatory variables take their mean values, the predicted probability of swap selection would be 4.4%, and would become 9.8% if the level of trade exposure rises by one standard deviation. US military allies enjoy a higher probability of selection for a swap arrangement than that of non-ally countries, and the difference in the probability is as high as 26.9%.

Our findings appear to be notably different from Aizenman and Pasricha (2010), who found that US bank exposure is a significantly positive contributor to the selection of emerging markets for swap agreements. One reason for this may be that the financial crisis originated in the US and threatened the solvency of banking institutions. Therefore, the swap lines then were aimed at providing liquidity lines to the economies where US bank exposure was high. During the COVID-19 crisis, despite large-scale falls in the stock markets and widespread dollar shortage, there was no acute systematic financial instability as during the GFC. However, the differences between the two results may be less stark than appears, as during the COVID-19 crisis, global supply chains got severely disrupted. Several papers have highlighted the increasing importance of global value chains in the past two decades and the associated intermingling of trade and finance (Boissay, Patel and Shin, 2020; Baldwin and Freeman; 2020). The COVID pandemic vividly illustrated the dependence of the US and the EU on the GVC as the source of critical medical supplies, and the sharp appreciation of the dollar in the early stages of the Covid-19 crisis may have had knock-on effects to trade finance from stress in the banking system. These considerations imply that we should take the econometric significance of the ‘trade factors’ in our regressions with a grain of salt: one needs micro data to identify more sharply the role of trade, finance and the interaction between the two.

⁵ In the sample used for the estimation with 63 economies, nine are provided swap lines, which means the crude probability of receiving swap lines is 14.5%. This gives us the cut-off for the “successful predictions” of 15%.

3. *Determinants of the size of liquidity lines via swap agreements and FIMA*

While the number of economies that have swap agreements with the US is limited (i.e., 14 in total with five central banks with long-standing arrangements and nine reactivated), the newly created FIMA facility is available to economies which do not have any swap agreements as long as they hold stocks of US Treasuries in their foreign exchange reserves which they can swap for dollars in the repo transactions. Therefore, the sum of the maximal amount of swap agreement with the Fed and the amount of US Treasuries in the foreign exchange reserves holding of an economy can be regarded as the potential availability of liquidity lines from the Fed. We estimate the determinants of the total size of liquidity lines available.

The size of liquidity lines available to economy i , y_i , is composed of swap lines, $SWAP_i$, and the FIMA line, $FIMA_i$, namely,

$$y_i = SWAP_i + FIMA_i . \quad (1)$$

We investigate the determinants of the available amount of liquidity lines using the estimation model below:

$$y_i = \alpha + X_i' \beta + \varepsilon_i \quad (2)$$

where y_i is the available amount of dollar liquidity and X_i' is a vector of candidate explanatory variables.

As for the size of the swap lines, $SWAP_i$ is straightforward because it is stipulated in the agreements. The maximal amount of swap lines is \$60 billion each for the RBA, BCB, BOK, BdM, MAS, SR, and \$30 billion each for the DNB, the NB, and RBNZ. We do not include the economies of the following five central banks: the BOC, BOE, BOJ, ECB, and SNB, in the estimation because there is no limit to the swap lines for these central banks.

Measuring the size of liquidity lines through the FIMA facility is not straightforward because there is no stipulation about the available amount of liquidity lines through the facility. Instead, the FIMA repo facility allows foreign central banks and other international monetary authorities to temporarily exchange US Treasuries held in their accounts at the Federal Reserve

Bank of New York for US dollars. Hence, the amount of dollar-denominated reserve assets is a good proxy for the dollar liquidity available to economy i .

To measure US dollar-denominated reserve assets, we need the data on the volume of reserve assets held by central banks and their currency composition. However, such data is notoriously limited.⁶ Recently, Ito and McCauley (2020) compiled a panel dataset on the shares of key currencies in foreign exchange reserves for about 60 economies in the 1999-2018 period.⁷ In order to obtain the holdings of dollar-denominated reserve assets, as an approximate of the availability of liquidity lines through FIMA, we multiply the dollar share in foreign exchange reserves as of 2018 from the Ito-McCauley dataset, with total reserves (minus gold) as of 2019.⁸

The candidate factors that may affect the availability of liquidity lines include the variables we tested in the previous exercise, namely, US bank exposure, the share of trade with the US, military alliance, and de jure financial openness. From the perspective of the US, it is rational to build a system that can provide liquidity lines for the economies that have more loans from US banks or that have more trade with the US.

In addition to these variables, we also test the variables for global financial exposure and the share of the economy in world trade. The rationale to test these variables is that the US might be willing to provide liquidity lines for the economies that do not necessarily have stronger financial or trade ties with the US per se. In other words, the US could be “altruistic” and willing to play the role of the guardian of the international economy by making dollar liquidity readily available through swaps or FIMA facility for large players in international finance or trade. We measure the level of global financial exposure ($Global_Fin_i$) with economy i 's sum of external assets and liabilities as a ratio to the world's external assets and liabilities over the period of 2005 through 2015, using the database compiled by Lane and Milesi-Ferretti (2001, 2007, and 2017). While a significantly positive estimate on $BankExp$ would imply that the US is more self-interested to make dollar liquidity readily available for economies with more consolidated claims

⁶ Heller and Knight (1978), Dooley et al (1989), and Eichengreen and Mathieson (2000) use the International Monetary Fund's (IMF) currency composition of official foreign exchange reserves (COFER). However, the data for individual countries are not publicly available.

⁷ Ito and McCauley (2020) collected the data from central banks' annual reports, financial statements, and other publicly available information sources.

⁸ If the 2018 data is not available, the dollar share data as of 2017 is used. The data availability for this exercise is determined by the Ito and McCauley dataset. Therefore, this regression exercise covers 51 economies.

of US banks, a significantly positive estimate on $Global_Fin_i$ would mean that the US is willing to make dollar liquidity available for economies playing a larger role in global finance. Parallel to $Global_Fin_i$, the variable of global trade exposure ($Global_Trade_i$), measured by the share of economy i 's sum of exports and imports in global trade (i.e., the world's sum of exports and imports), would show whether or not the US is altruistic to maintain global trade order by providing liquidity to economies that have larger presence in international trade.

We also test the dummy for China since the country's holding of dollar-denominated assets is by far larger than the rest of the sample economies. As in the previous exercise, all the explanatory variables are sampled as of the end of 2019. We run a cross-sectional OLS regression for 51 economies.

The results presented in Table 3 indicate that higher US bank exposure to an economy led to a greater liquidity from the swap agreement. Interestingly, the variable for US bank exposure alone explains almost 60% of the variation of the availability of dollar liquidity. Also, an economy with more trade with the US tends to have more accessibility to dollar liquidity, additionally explaining another 40% of the variation of dollar liquidity availability. Just the two variables of US bank exposure and the share in US trade explain 98% of the variation of the accessibility of dollar liquidity, perhaps because they determine the amount of dollar-denominated assets held in FX reserves.

Columns (3) through (6) also indicate that the US is altruistic in the sense that it makes dollar liquidity available for global major trading centers regardless of whether those economies are major trading economies with the US. However, the share in global finance does not matter for liquidity accessibility. These findings suggest that, as we found in the previous exercise, trade plays an important role in terms of determining which economies have better access to dollar liquidity. The estimates of the three variables, US bank exposure, the share in trade with the US, and global presence of trade, are persistently statistically significant across the different models and explain almost all of the variation in the availability of dollar liquidity. The extent of financial openness does not matter for the size of dollar-liquidity available. China appears as an outlier, but inclusion of the dummy does not materially change the estimates of the other variables.

4. *Determinants of the size of US dollar auctions by central banks*

The actual use of liquidity lines may differ from the availability of liquidity lines. Both the availability and the use of US dollar liquidity may affect market perceptions and conditions, which we will investigate in section 4. In this section, we investigate the factors that determine the amount of US dollars auctioned by central banks in their domestic markets. Most of these auctions used the Fed liquidity lines as the source of the US dollar auctioned by central banks. The amount of dollars auctioned was largely determined by market conditions.⁹

We regress the amount of US dollars auctioned on a set of candidate variables. They include: cumulative depreciation (*Cuml_fx*), which is the rate of change in the local currency value per dollar with respect to the average local currency value during the first two weeks of January 2020; exchange rate volatility (*fx_vol*), the standard deviations of the rate of depreciation over rolling 14-day windows; stock market volatility (*stk_vol*), the standard deviations of the rate of stock market total return over rolling 14-day windows; and the level of financial instability measured by the Chicago Board Options Exchange Volatility Index (*VIX*) in log. We also test the variable for the number of new cases of COVID infection (*COVID*) measured by the moving average coronavirus infection cases per million over 7 days, and the mobility index (*MOBILITY*) to capture the possible impact of economic activities on daily basis. The estimation model also includes the dummy that takes the value of unity for Germany, U.K., and Japan. This is because the volumes of auctions central banks of these economies conduct are at times much larger than the rest of the economies. For this estimation, we apply an OLS estimation model to the daily panel data of 42 economies for the period of January 15, 2020 through May 29, 2020.¹⁰

⁹ Some central banks, including the major central banks, either did not notify a maximum limit on the auctions, or notified an amount large enough that the amount auctioned was determined by the bids received. There were only a few cases – in Colombia, India, Indonesia, and Mexico – where the amount bid was larger than the amounts notified, and therefore accepted, by the central banks.

¹⁰ One may suggest that we should use the Heckman two-step selection model (1976), in which the first step is the probit estimation of the probability of auctioning and the second step is the OLS to estimate the amount of the auctions. However, as Table 1 makes it clear, the timing of auctions is pre-announced, i.e., it is not determined by economic and non-economic conditions. It is rather determined mechanically. Hence, we think estimating the probit model prior to the OLS estimation is inappropriate.

The estimate on the cumulative depreciation rate is significantly negative, in the results reported in columns (1) and (2) of Table 4. This suggests that central bankers facing their currency *appreciating* cumulatively compared to the beginning of January 2020 auctioned more US dollars in their domestic markets. The estimate on the variable for exchange rate volatility is significantly positive, suggesting when their currency's value is unstable, central bankers auction more US dollars. More global financial instability also increased the amount of US dollars auctioned by the monetary authorities. In column (2), we add the variable for the number of new COVID cases as well as the mobility index. These variables that are more directly related to the pandemic are not found to be determinants for the volumes of auctions.

In columns (3) and (4), we include only non-zero observations of auction volumes in the sample.¹¹ Not surprisingly, the sample size becomes much smaller, and the sample is composed only of 15 economies. In this more restricted estimation, the variables for the cumulative depreciation rate and exchange rate volatility now become statistically insignificant. Only the VIX variable and the dummy for Germany, U.K, and Japan remain statistically significant. These findings suggest that among the economies that auction US dollars, the volume of auction is a function of only the degree of global financial instability, or more precisely, the US stock market volatility. The higher degree of global financial instability, or the more volatility the US stock market is experiencing, the more volumes of dollar auctions central banks conducted.

5. The economic impacts of Federal Reserve liquidity lines and US dollar auctions

While providing dollar liquidity through a swap agreement or the FIMA facility can have economic impacts through alleviating dollar liquidity shortage, the mere announcement of these liquidity facilities can also have economic impacts because such a policy announcement would affect economic agents' expectations and consequently their behavior (confidence channel).

In this section, we investigate whether and how the announcements of the swap agreements or the creation of the FIMA facility affect economic variables, namely, credit default swap (CDS) spread, cross currency basis (deviations from covered interest parity), government bond yields, and the local currency exchange rate while controlling for other domestic and international economic conditions and policies. We also examine the domestic and spillover

¹¹ That is, when there is no auction in a day for an economy, the cell for the day and the economy would be recognized as a missing variable.

effects of US dollar auctions held by central banks, and whether these effects are greater for economies that are more exposed to the US in terms of trade or financial transactions.

5.1 Baseline model

To capture the size and the persistence of the impacts on economic variables, we employ the local projection method (Jordà, 2005) to the sample of 43 economies and run a series of regressions for different horizons, $r = 0, 1, 2, \dots, p$ as follows (IMF, 2020):^{12,13}

$$\begin{aligned}
\Delta Y_{i,t-1 \rightarrow t+p} = & \sum_{r=0}^p \beta_1^{p,r} \mathbf{Swapfima}_{i,t+p-r} + \sum_{r=0}^p \beta_2^{p,r} \mathbf{Auction}_{owni,t+p-r} \\
& + \sum_{r=0}^p \beta_3^{p,r} \mathbf{Auction}_{Major}_{i,t+p-r} + \sum_{r=0}^p \beta_4^{p,r} \mathbf{Other Controls}_{i,t+p-r} \\
& + \sum_{l=1}^3 \gamma_1^l \mathbf{Swapfima}_{i,t-l} + \sum_{l=1}^3 \gamma_2^l \mathbf{Auction}_{owni,t-l} + \sum_{l=1}^3 \gamma_3^l \mathbf{Auction}_{Major}_{i,t-l} \\
& + \sum_{l=1}^3 \gamma_4^l \mathbf{Other Controls}_{i,t-l} + \delta \mathbf{COVID}_{t-1} + \mu_i + w_s + \varepsilon_{i,t+p}
\end{aligned}
\tag{3}$$

$\Delta Y_{i,t-1 \rightarrow t+p}$ is the cumulative percentage point change from $t-1$ to $t+p$ in economy i 's currency per US dollar; cross-currency basis for economy i 's currency against US dollar; economy i 's 10-year sovereign bond yield; or the credit default swap (CDS) spread for economy i .

Swapfima is a dummy variable that takes the value of one on the days of Fed swap announcements for swap recipients, and on the day of the FIMA facility announcement for all economies. That is, when the Fed makes an expansionary change in the swap policy, the dummy takes the value of one for the counterpart economy in the swap agreement. For example, the Fed

¹² The sample includes Canada, the U.K., Japan, Switzerland, and the euro area. For the euro area, Germany is included as the representative economy.

¹³ The model framework also follow Teulings and Zubanov (2014) who include not just the lagged variables of control variables but also their leads (i.e., $\sum_{r=0}^p \beta_j^{p,r} X_{i,t+p-r}$ where X is an explanatory variable). They argue that it would prevent the estimates from being biased.

reduced swap pricing and introduced 84-day operations with five major central banks on March 15, 2020. On March 19, the Fed reactivated swap lines with nine central banks. On March 20, BoC, BoE, BoJ, ECB, and SNB took a coordinated action to enhance the effectiveness of the standing dollar swap by increasing the frequency of 7-day maturity operations from weekly to daily. *Swapfima* takes the value of one for relevant counterpart economies and swap announcement dates. When the FIMA facility was created on March 31, 2020, in contrast, the dummy variable takes the value of one for *all* the sample economies because this policy is relevant *all* economies. All these policy actions are meant to provide more dollar liquidity and therefore stimulative actions.¹⁴

In the baseline specifications, *AuctionOwn* is the dummy for the dates when economy *i*'s central bank auctions of US dollars whereas *AuctionMajor* is a dummy that takes the value of one for the dates when major central banks (ECB, BOE, SNB, and BOJ) auctioned US dollars. This variable aims to capture the spillover effects of auctions by the major central banks. In robustness checks, we redefine, *AuctionOwn* and *AuctionMajor* to use the auction amounts (the amount accepted in the auctions) instead of dummies for auction days.

The model controls for other stimulus policies that are supposed to affect liquidity and include the following variables in the vector *Other Controls*: *QE* is the dummy for quantitative easing (QE) implemented by the Fed on March 23. *NPR* is a decline in the monetary policy rates of the sample economies (i.e. the negative of the change in the policy rate). We also control for global financial market conditions using the Chicago Board Options Exchange Volatility Index (*VIX*) in log. We control for changes in sovereign credit ratings by any of the big three credit rating agencies, Standard and Poor's, Moody's, or Fitch. The variable for the change in sovereign credit ratings takes the value +1 on the days when there is a ratings upgrade by any of the agencies, -1 for the days with a downgrade, and 0 otherwise. As another factor that can affect expectations, we control for the pandemic situation with the first lag of the 7-day moving average of new corona cases per million (*COVID*).

¹⁴ We decided not to assign a separate dummy for each of the Fed policy actions. Because these policies were implemented on close dates to one another, the impact of individual policy actions is difficult to identify – the lags and leads in the estimation model make it more difficult.

The estimation includes economy fixed effects and weekly time fixed effects is conducted for business days for the period of January 2 through May 31, 2020.¹⁵ We employ the local projection method that estimates a series of regressions for each horizon p for each variable. Here, we assign p to be 5, that means we attempt to capture the full dynamics of each of the four dependent variables in the aftermath of policy announcements or actions by central banks over the course of five business days. Standard errors are robust. To focus on the dynamics of the economic variables in response to a policy shock, we focus on reporting the cumulative impulse response functions (IRFs) rather than discussing the estimated coefficients.¹⁶

We have two practical reasons to use the local projection model over the VAR model. First, to economize the number of estimates, we employ two-way fixed effects, namely, economy-fixed effects and weekly time fixed effects. Including these fixed effects in a VAR model would complicate the estimation. Economy-fixed effects control for time-invariant, or slowly changing, characteristics of each sample economy (e.g., the level of development of the medical and insurance systems, economies' debt levels, the tendency for fiscal interventions). Weekly fixed effects control for common, global waves of the virus infections or related news. Including these fixed effects helps reduce the number of estimated parameters. These fixed effects also allow us focus on the estimates of the variables of our interest, i.e., the dummies for the announcements or the implementation of swap and other stimulus policies. These fixed effects are easier to include in the estimation model and to interpret when the local projection model is used, but not so much with a VAR model.

Second, using the IRF based on the local projection model is more appropriate when the estimation involves nonlinear estimates. As we discuss later, we test whether the impact of swap and other stimulus policies varies with US trade or financial exposure with the recipient economies. To test this, we include interaction terms between US trade or financial exposure and the policy variable of our interest. While nonlinear VAR models exist, the estimation and

¹⁵ The first policy action related to swap operations took place on Sunday, March 15. To capture the impact of the policies, we assign the value of one in *Swapfima* on March 16.

¹⁶ Auerbach and Gorodnichenko (2013), Ramey and Zubairy (2018), Sever and others (2020) and many others have applied the local projection model to macroeconomic analyses.

interpretation of their estimates is highly complex. With the local projection model, this kind of exercise can be done with ease.

5.2 Baseline results: Announcement effects of Federal Reserve liquidity lines

The main purpose of Fed swap lines or the FIMA facility was to increase US dollar liquidity globally and stabilize foreign dollar markets. Panel (a) of Figure 4 shows that the currencies of recipient economies appreciate on the day of the policy announcement and days 4 and 5, which means that the US dollar depreciates against these currencies on those days, consistent with the policy objective. The announcements of swap lines or FIMA do not seem to affect the three-month cross-currency basis, which is a more direct measure of dollar shortage (Figure 4(b)). However, it must be noted that the data for this variable is available for only 21 currencies. The finding that the US dollar depreciates against the currencies of swap/FIMA recipients following the announcements of these policies does signify that the policies mitigated the dollar shortage.

The CDS spreads for swap/FIMA recipients improve when the Fed shows its willingness to provide dollar liquidity (Figure 4(c)). The persistent decline in the CDS spreads starts immediately on the day when the policy is announced, and the spread improvement lasts for the following two business days. We can interpret this finding as evidence that the (expected) mitigation of dollar constraint would reduce the default risk in general.

Fed swap lines could have an expansionary impact on the long-term interest rates of recipient economies, through a reduction in default risk. Figure 4(d) shows that the announcements of swap lines put downward pressure on the ten-year government bond yields, but the impact is not statistically significant.

The estimated impacts of other variables are also consistent with theoretical predictions. For example, a rise in VIX leads to a relatively large depreciation of the home currency, of about 2 percentage points, which lasts 3 days (Figure 5(a)). This reflects a tendency for investors to rush into dollar-denominated assets when the financial markets are exposed to a negative global shock, which leads to dollar appreciation. Quantitative easing (QE) by the Fed, on the other hand, leads to a persistent and large appreciation of the other currencies and a US dollar depreciation, as expected. The expected result can also be observed in the estimated impact of QE on the non-US ten-year government bond yields (Figure 5(b)). Neither VIX nor QE seems to

have any impact on the CDS spread (Figure 5(c)). A fall in the domestic monetary policy rate does not have a significant impact on any of the economic variables, consistent with the results in Sever and others (2020).

5.3 Domestic and spillover effects of US dollar auctions

This estimation model also allows us to examine the impact of central banks' swap auctions to supply dollar liquidity to the markets, on financial variables. Most of the auctions are pre-announced, and often, but not always, the source of dollars being auctioned is from the Federal Reserve swap lines or FIMA.¹⁷ We assess the impact of US dollar auctions by economy *i*'s own central bank/monetary authority on the economic variables of our interest. We also examine the spillovers of US dollar auctions by the four major central banks (i.e., BOE, BOJ, ECB, or SNB) on other economies' financial variables.

On the days when the central banks of our sample economies conduct US dollar auctions, their home currencies appreciate on days three and four, perhaps reflecting the first settlement of the auctions, but the cumulative effect is not significant on day 5. (Figure 6 (a)). Own central banks' dollar auctions therefore have a short-lived effect of alleviating pressure on the domestic currency. When any of the major central banks conducts FX auctions, on the other hand, there is an immediate appreciation of *other* economies' currencies against the US dollar, with its impact persistently becoming larger through day 5. These findings suggest that foreign exchange swap auctions by the major central banks are very effective and have implications beyond the home economies.

FX auctions do not appear to affect the dynamics of the ten-year government bonds yields or the CDS spread, except for a small but short-lived ameliorative impact of major central bank auctions on government bond yields of other economies (Figures 6 (b), (c)).

¹⁷ For example, the Reserve Bank of India announced that it will conduct US dollar auctions on March 12, 2020, without specifying the source of the US dollars, which likely were from its own reserves, as FIMA had not yet been announced and the RBI does not have swap line with the Fed. The Hong Kong Monetary Authority announced on April 22, 2020 that it will conduct US dollar auctions using funds obtained from the FIMA.

5.4 Interactive analysis: Does US-exposure matter for impact of dollar auctions?

How the US dollar swap or auction policies affect the dynamics of the economic variables of our interest can depend on whether and to what extent the economies are exposed to the US in terms of trade or financial transactions. Rose and Spiegel (2012) find that the impact of swap auctions of dollar assets by foreign central banks is larger for economies that have more trade or financial linkages with the US

We now examine whether and to what extent the level of trade or financial linkage with the US affects the impact of US dollar swap or auction policies by including in the estimation model the interaction terms as:

$$\begin{aligned} \Delta Y_{i,t-1 \rightarrow t+p} = & \sum_j \sum_{r=0}^p \beta_j^{p,r} X_{i,t+p-r}^j + \sum_j \sum_{r=0}^p \delta_j^{p,r} X_{i,t+p-r}^j \cdot EXP_i \\ & + \sum_j \sum_{l=0}^3 \gamma_j^l X_{i,t-l}^j + \sum_j \sum_{r=0}^p \theta_j^l X_{i,t-l}^j \cdot EXP_i + \delta COVID_{t-1} + \mu_i + w_s \\ & + \varepsilon_{i,t+p} \end{aligned} \quad (4)$$

where EXP is either *BankExp* (exposure of US banks to individual economies) or *TradeShare* (the share of economy i in total US goods imports and exports).¹⁸ The estimates of our focus are $\delta_j^{p,r}$. If the extent of trade or financial exposure matters, this estimate will be significant with a sign that would enlarge the absolute magnitude of *Swampfima* or other policy shock variables (i.e., FIMA announcement, and own or major central bank auctions). X^j are each of the explanatory variables in the baseline model other than COVID, i.e. *Swampfima*, *Auction_{own}*, *Auction_{Major}* and *Other Controls*.

Figure 7 (a) illustrates the interactive effects of swap-related policies and bank exposure. That is, $(\beta_1^{p,r} + \delta_1^{p,r} \cdot EXP_{i,t+p-r}) \cdot Swampfima_{i,t+p-r}$ when EXP is *BankExp*. To make the

¹⁸ We do not include the level term of EXP , mainly because the preliminary test showed that neither *BankExp* nor *TradeShare* enters the estimation significantly. Rose and Spiegel (2012) do not include the level terms for the same reason.

interpretation easier, we draw two lines, one for the case where *BankExp* takes the 75th percentile value (blue line) and the other for the 25th percentile value (red line). From the two lines barely apart from each other, we can see that the extent of bank exposure does not affect the impact of *Swampfima*. $\hat{\delta}_1^{p,r}$ is statistically insignificant. The impacts of swap auctions by either individual economies' central banks or the major central banks do not depend upon bank exposure. The lack of statistical significance is not just the case for the impacts on the exchange rate, but also on the sovereign debt yield or the CDS spread (Figures 8 and 9). In fact, most of $\hat{\delta}_j^{p,r}$ turn out to be statistically insignificant.¹⁹

When we include *TradeShare* for *EXP*, again, in most of the cases, $\hat{\delta}_j^{p,r}$ is statistically insignificant, indicating that the extent of trade exposure to the US does not affect the impact of swap policies or auctions.

These estimation results give us an answer to the question of whether the effects of liquidity-providing policies differ depending on the extent of trade or financial exposure to the US. The answer is no. This finding is different from that of Rose and Spiegel (2012). We conclude that US liquidity-providing policies are indiscriminatory, possibly benefiting economies regardless of the existence of trade or financial ties with the US. That is consistent with the claim that the US Fed is the lender of the last resort.

6. Robustness checks

The results presented in section 5 are robust to several changes in specification.²⁰ First, we increased the number of lags and leads in the model to 11 leads and 6 lags. The results remain robust, and the announcement effect of the swap lines and FIMA on exchange rates against the US dollar persists on day 11, while the impact of the auctions by the major central banks persists until day 10.

Second, the estimation results are robust to using alternative control variables that measure the severity of the pandemic. We used total number of COVID-19 cases instead of new cases per million, controlled for lockdowns and for changes in the level of mobility with respect to the pre-

¹⁹ Therefore, to avoid the figure cluttered with many lines, we do not show confidence intervals.

²⁰ The results are available on request.

pandemic period. These variables are not significant, and do not affect the results for the variables of interest as described in the previous section.

Third, we used the US dollar amounts auctioned by central banks (i.e. the US dollar value of bids accepted) instead of the dummy to represent the days when auctions took place. When we use the auction amounts rather than the auction dummies, we find that the auctions by the major central banks have a small but statistically significant impact on cross-currency basis, indicating a reduction in the extent of dollar shortage for the day of the auction and the following day. Auctions by own central banks do not have any impact on the cross-currency basis. The results for the other variables remain unchanged from those described in section 5.

7. *Concluding remarks*

The outbreak of the COVID-19 pandemic instigated a financial turmoil in March 2020. As in the previous episodes of financial instability, the uncertainty made investors rush to hold US dollar-denominated assets, creating a dollar shortage. To prevent this situation from morphing into a global systematic financial crisis, the Fed made US dollar liquidity readily available through reinforcing or reactivating central bank swap lines and creating the FIMA repo facility.

This paper investigates the motivations for and effects of US dollar liquidity provision with the following questions: First, what factors led the Fed to select nine economies as swap partners as it did at the time of the GFC? Second, what factors determined the total availability of liquidity lines (swaps and the FIMA facility) from the Fed? Third, what domestic conditions determined the size of dollar auctions by central banks? Fourth, what were the announcement effects of the Fed liquidity arrangements and the domestic and spillover effects of dollar auctions by central banks? Fifth, did the economic impacts of the US dollar liquidity provision differ depending on the degree of financial or trade exposure to the US?

We find that the Fed chose to reactivate swap agreements with nine economies because of these economies' large trade ties with the US. This result is in contrast with the previous episode of dollar shortage in 2008 when the US signed swap agreements with emerging economies due to their financial ties with the US. The existence of formal military alliances was also a determinant for the Fed to reactivate the swaps for these economies. Economies with strong financial and trade ties with the US tended to have more access to dollar liquidity lines. Global

major trading centers also had greater access to US dollar liquidity via the Fed, regardless of whether they had more financial or trade ties with the US. The amounts auctioned by central banks were larger for currencies that faced greater exchange rate volatility, and when global financial conditions were more unstable, as captured by a higher VIX.

The announcements of swap-related policies had meaningful impacts on economic variables; they led to appreciation of the partner currencies against the US dollar, and a decline in the economies' CDS spreads and ten-year government bond yields. US dollar auctions by economies' own central banks led their home currencies to appreciate. Although this effect was temporary. US dollar auctions by the major central banks (BoE, ECB, BoJ and SNB) had more persistent appreciation effects on the home currencies of the non-major economies. That indicates that liquidity policies taken by the major central banks have important spillover effects on other economies.

One may conjecture that the economic impacts of swap and other liquidity policies or auctions can be greater for the economies that have financial or trade ties with the US. However, our findings suggest that dollar liquidity policies have egalitarian impacts irrespective of the extent of financial or trade ties with the US.

Tables and Figures

Table 1: Chronology of Fed swap lines and FIMA announcements

Date	Policy Actions	Relevant Central Banks
March 15	Reduced Swap Pricing	Bank of Canada (BoC), Bank of England (BoE), Bank of Japan (BoJ), European Central Bank (ECB), Swiss National Bank (SNB)
	Introduced 84-day operations	BoE, BoJ, ECB, SNB
March 19	Reactivate temporary swap lines with nine other central banks	Reserve Bank of Australia (RBA), Banco Central do Brasil (BCB), Bank of Korea (BoK), Banco de Mexico (BdM), Monetary Authority of Singapore (MAS), and Sveriges Riksbank (SR) with the maximal lines of \$60 billion. Danmarks Nationalbank (DNB), Norges Bank (NB), and Reserve Bank of New Zealand (RBNZ) with the maximal lines of \$30 billion.
March 20	Increased frequency of one-week operations to daily	BoC, BoE, BoJ, ECB, SNB
March 31	Established FIMA repo facility	Foreign International Monetary Authority (FIMA) account holders

Notes: Bank of Canada, Bank of England, Bank of Japan, European Central Bank, Swiss National Bank have established permanent swap arrangements with the Fed since the Global Financial Crisis. There is no limit to the swap amount for these central banks.

# of economies	42	41	15	15

Notes: * $p < 0.1$; ** $p < 0.05$; *** $p < 0.01$. Columns (1) and (2) include observations when there is no auction taking place (instead of zero auctions being identified as missing variables). Columns (3) and (4) include only non-zero observations of auction volumes. That is, when there is no auction in a day for an economy, the cell for the day and the economy would be recognized as a missing variable. DE, JP, and UK refer to Germany, Japan, and United Kingdom respectively. MA refers to 7-day backward looking moving average.

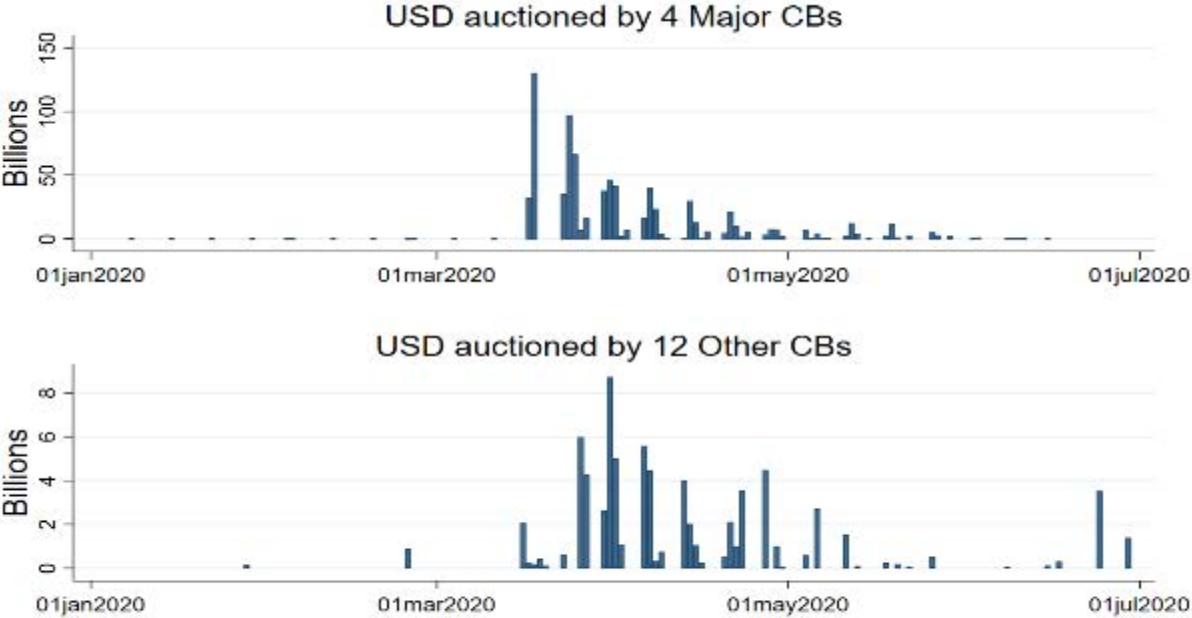

Figure 1: Cross-currency basis (CIP deviations) widened during the COVID-19 crisis

3-month swaps, basis points

Source: Bloomberg, JP Morgan

Figure 2: Many advanced and emerging-market central banks auctioned US dollars during the COVID-19 crisis

Major central banks: BoE, BoJ, ECB, SNB
 Other CBs: Australia, Chile, Colombia, Denmark, Hong Kong, India, Indonesia, Korea, Mexico, Norway, Singapore, Sweden

Figure 3: Outstanding dollar liquidity lines with Fed peaked between March-May 2020

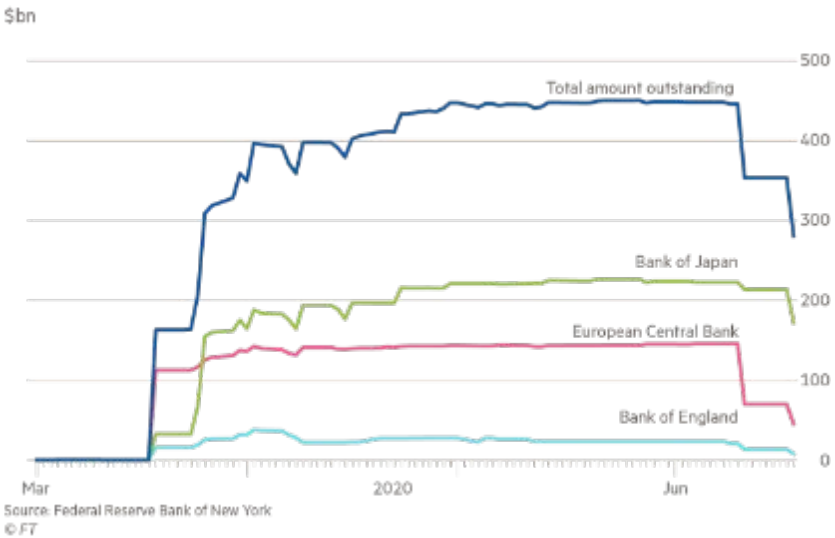

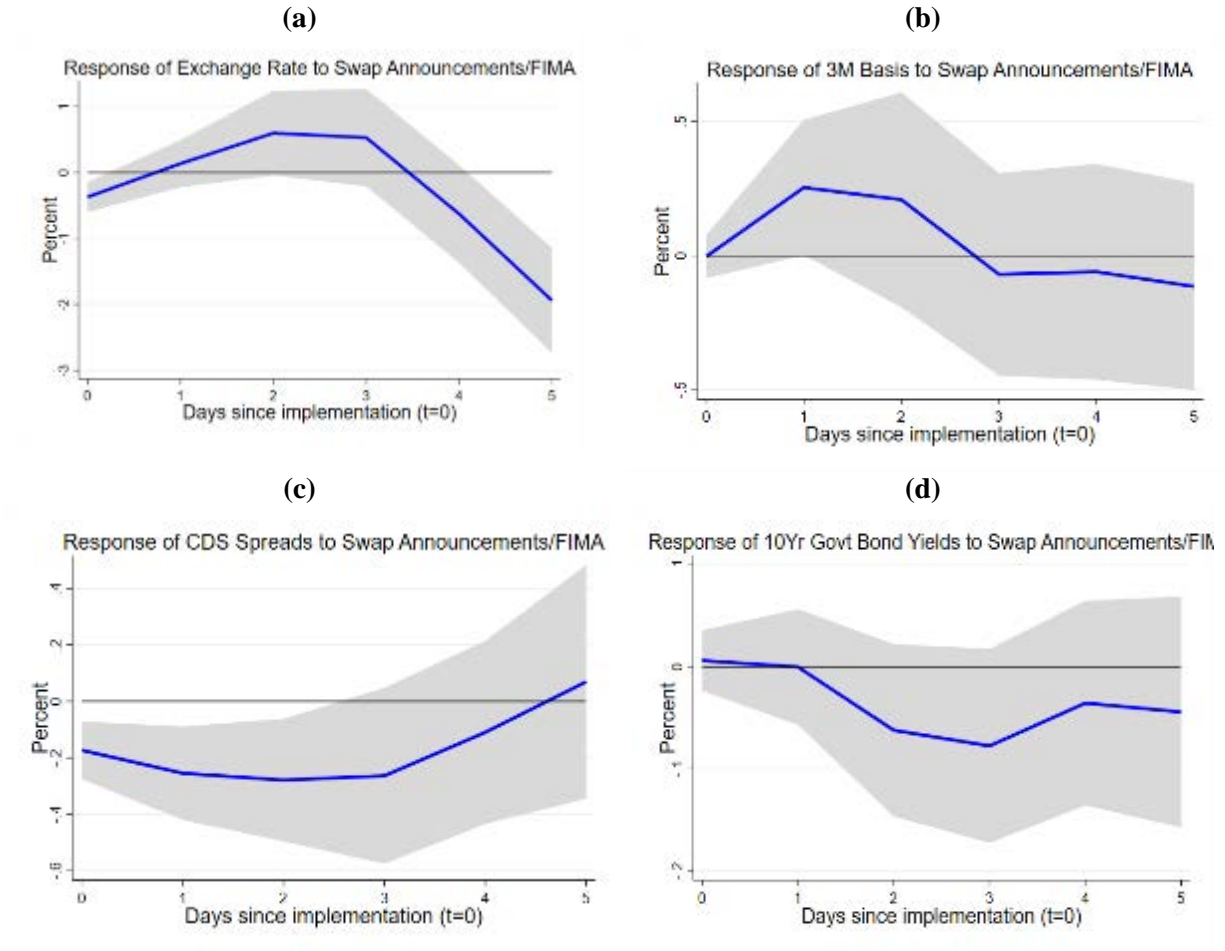

Figure 4: Estimated effect of the announcements of the swap agreements and FIMA on the rate of depreciation of the home currency

Notes: The figure illustrates the accumulated impact of (a) the rate of depreciation of the home currency, (b) the change in 3-month cross-currency swap basis, (c) the change in the CDS spread to the Fed (d) the change in the 10-year government bond yield on the Fed announcing swap expansions or the establishment of the FIMA facility. The announcement takes place at $t=0$, and the cumulative impulse response functions are illustrated for the next five business days. The units for the y-axis are percent.

Figure 5 (a): Estimated effects of VIX, QE and domestic monetary policy easing on the depreciation rate of the home currency

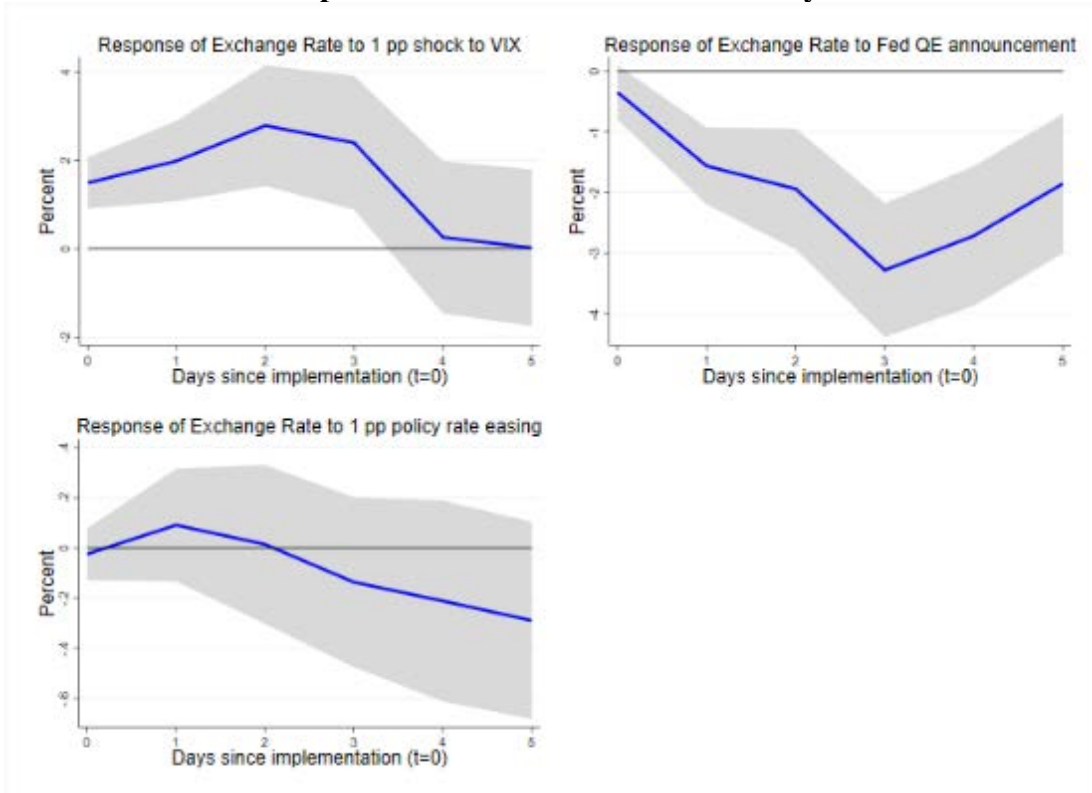

Figure 5 (b): Estimated effects of VIX, QE and domestic monetary policy easing on government bond yields

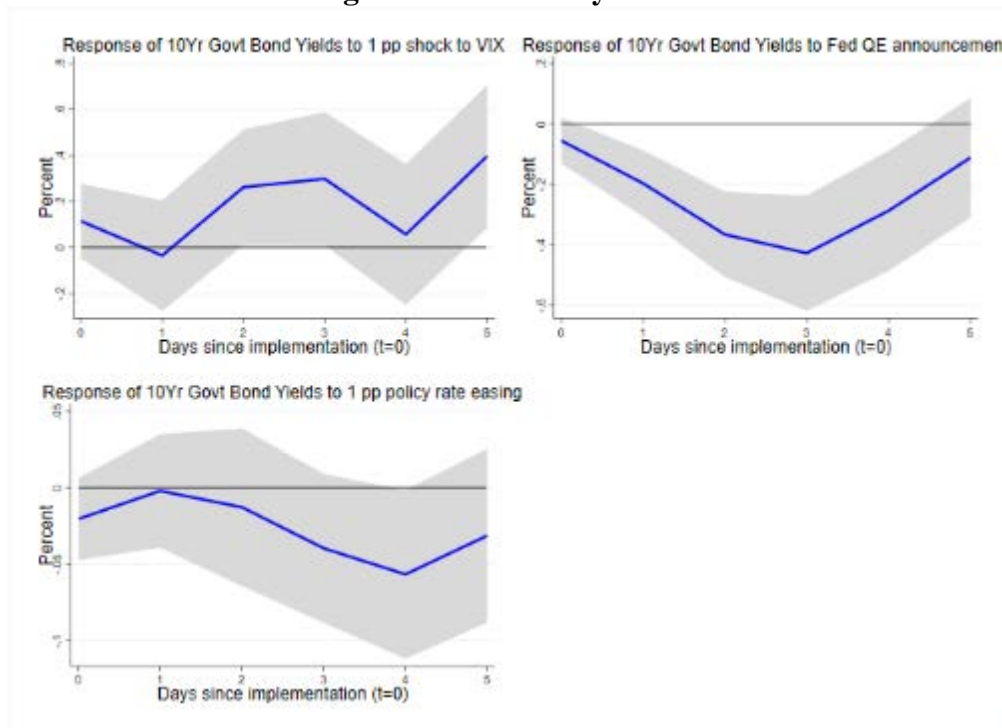

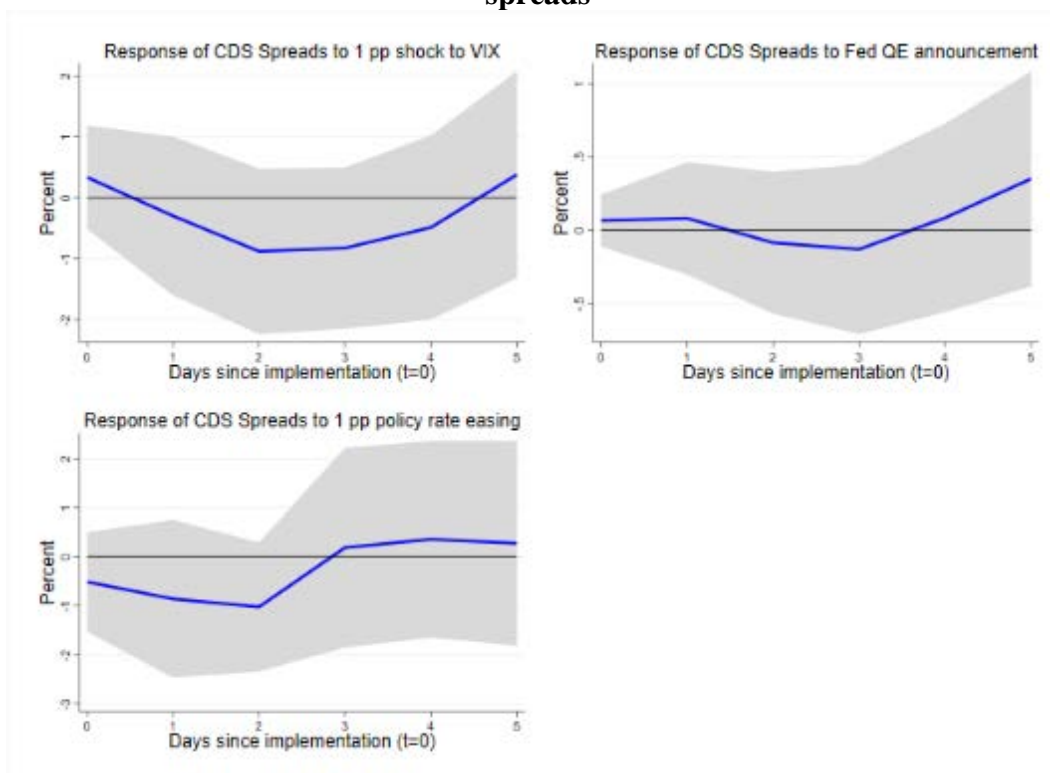

Figure 5 (c): Estimated effects of VIX, QE and domestic monetary policy easing on CDS spreads

Notes: The announcement takes place at $t=0$, and the cumulative impulse response functions are illustrated for the next five business days. The units for the y-axis are percent.

Figure 6 (a): Estimated effects of FX auctions on the depreciation rate of the home currency

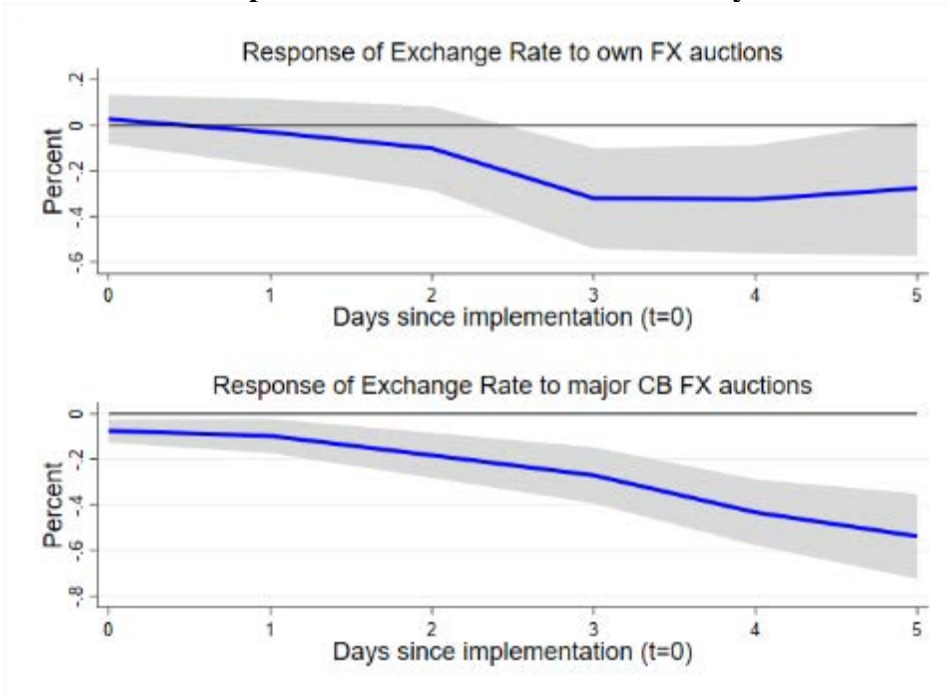

Figure 6 (b): Estimated effects of FX auctions on the change in the ten-year government bond yields

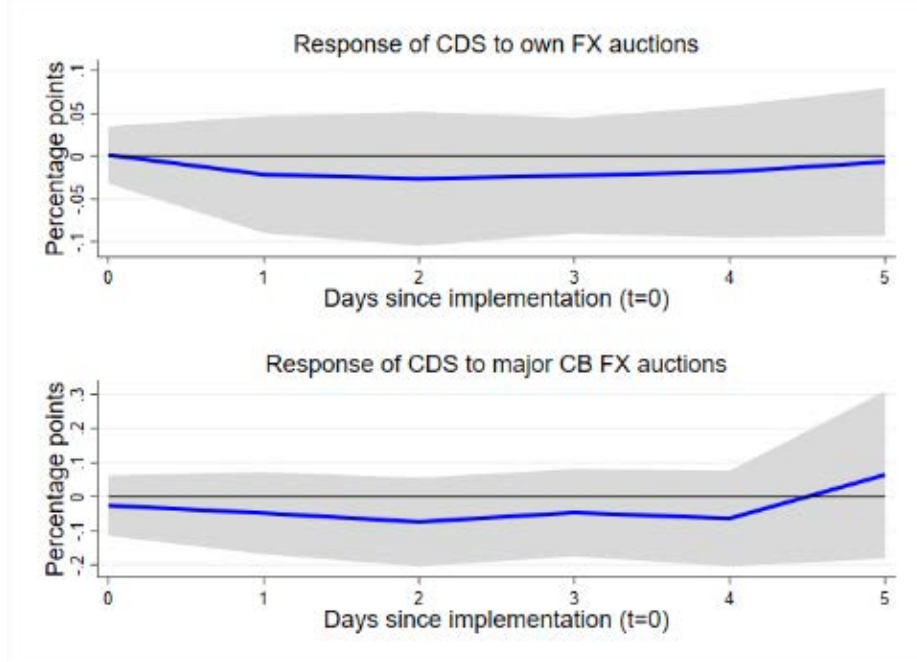

Figure 6 (c): Estimated effects of FX auctions on the change in the CDS spread

Notes: The announcement takes place at $t=0$, and the cumulative impulse response functions are illustrated for the next five business days.

Figure 7 (a): Interactive effects of swaps and financial exposure on the exchange rate

Figure 7 (b): Interactive effects of foreign exchange auction and financial exposure on the exchange rate

Notes: The announcement takes place at $t=0$, and the cumulative impulse response functions are illustrated for the next five business days.

Figure 8 (a): Interactive effects of swaps and financial exposure on the 10-year government bond yield

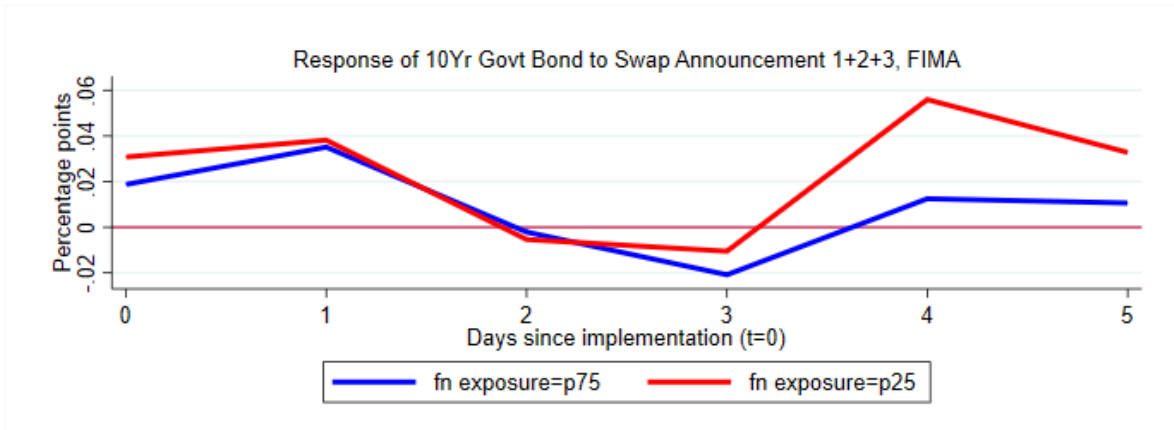

Figure 8 (b): Interactive effects of foreign exchange auction and financial exposure on the 10-year government bond yield

Notes: The announcement takes place at $t=0$, and the cumulative impulse response functions are illustrated for the next five business days.

Figure 9 (a): Interactive effects of swaps and financial exposure on the CDS spread

Figure 9 (b): Interactive effects of foreign exchange auction and financial exposure on the CDS spread

Notes: The announcement takes place at $t=0$, and the cumulative impulse response functions are illustrated for the next five business days.

Appendix I: List of economies

Argentina	India	Qatar
Australia ^S	Indonesia	Romania
Azerbaijan	Israel	Russian Federation
Bangladesh	Japan ^S	Saudi Arabia
Bolivia	Kenya	Singapore ^S
Bosnia and Herzegovina	Korea, Rep. ^S	South Africa
Brazil ^S	Kyrgyz Republic	Sri Lanka
Bulgaria	Macedonia	Sweden ^S
Canada ^S	Malawi	Switzerland ^S
Chile	Malaysia	Taiwan
China	Mexico ^S	Tajikistan
Colombia	Moldova	Tanzania
Costa Rica	Mozambique	Thailand
Croatia	Namibia	Tunisia
Czech Republic	New Zealand ^S	Turkey
Denmark ^S	Nigeria	Ukraine
Ecuador	Norway ^S	Uganda
Euro area ^S	Pakistan	United Arab Emirates
Georgia	Papua New Guinea	United Kingdom ^S
Ghana	Paraguay	Uruguay
Hong Kong, China	Peru	Venezuela
Hungary	Philippines	Zambia
Iceland	Poland	

Note: The superscript “S” refers to the economies that are given swap lines with the Fed.

Appendix II: Data Sources

We provide below a listing of the mnemonics for the variables used in the analysis, descriptions of these variables and the source(s) from which the primary data for constructing these variables were taken.

Variable	Variable description	Source
<i>BankExp</i>	Consolidated claims of US banks on individual economies divided by the consolidated claims of US banks on all economies as of December 2019.	BIS Consolidated Banking Statistics
<i>TradeShare</i>	Total US goods trade with the individual economy as a share of US goods trade with the world as of December 2019.	IMF Direction of Trade
<i>KAOPEN</i>	Chinn-Ito index of financial openness	Chinn and Ito (2006, 2008)
<i>ALLIANCE</i>	Dummy for economies that are in a formal military alliance with the US	CIA Factbooks
<i>Global_Fin</i>	Level of global financial exposure, measured by economy <i>i</i> 's sum of external assets and liabilities as a ratio to the world's external assets and liabilities over the period of 2005 through 2015.	Lane and Milesi-Ferretti (2001, 2007, and 2017)
<i>Global_Trade</i>	Level of global trade exposure measured by the share of economy <i>i</i> 's sum of exports and imports in global trade (i.e., the world's sum of exports and imports).	IMF Direction of Trade Statistics
<i>Cuml_fx</i>	Cumulative exchange rate. the rate of change in the local currency value per dollar with respect to the average local currency value during the first two weeks of January 2020.	Haver
<i>fx_vol</i>	Exchange rate volatility, measured by the standard deviations of the rate of depreciation over rolling 14-day windows.	Haver
<i>stk_vol</i>	Stock market volatility, measured by the standard deviations of the rate of stock market total return over rolling 14-day windows.	Haver
<i>VIX</i>	Chicago Board Options Exchange Volatility Index (<i>VIX</i>) in log	https://www.cboe.com/tradable_products/vix/
<i>COVID</i>	7-day moving average of new COVID-19 cases per million population	Johns Hopkins University Coronavirus Resource Center (https://coronavirus.jhu.edu/)
<i>MOBILITY</i>	7-day moving average of the change in mobility. The change in mobility is the percentage change from baseline, of workplace mobility from Google Global Mobility Report for all economies except China. For China, the Baidu city movement intensity data for Wuhan is used to construct the percentage change in mobility from the baseline of first two weeks in January 2020.	Google Global Mobility Report; Baidu City Movement Intensity data
<i>Lockdowns</i>	Number of measures introduced/extended less number of measures phased-out, for the following types of measures: Border closures, closure of businesses and public services, complete border closures, curfews, domestic travel restrictions, full lockdowns, international flights suspension, isolation and quarantine policies, limit public gatherings, partial lockdowns, state of emergency declared.	ACAPS COVID-19 Government measures dataset: https://www.acaps.org/covid-19-government-measures-dataset

Variable	Variable description	Source
<i>Ratings</i>	Change in sovereign credit ratings by Fitch, Moody's or Standard and Poor's (S&P). The variable takes the value +1 on days that see a ratings upgrade by any of the agencies, -1 on days with a downgrade and 0 otherwise.	<u>Fitch, Moody's, and S&P</u>
<i>Swapfima</i>	Dummy variable that takes the value of one on the days of Fed swap announcements for the swap recipients, and on the day of the FIMA facility announcement for all economies.	Fed's website
<i>Auction_Own</i>	Dummy for when economy <i>i</i> 's central bank auctions US dollars	Websites of the sample economies' central banks
<i>Auction_Major</i>	Dummy that takes the value 1 for days when US dollars are auctioned by major central banks (ECB, BOE, SNB, and BOJ) for economies other than those of these four central banks.	Websites of the sample economies' central banks
<i>QE</i>	Dummy for the implementation of quantitative easing (QE) by the Fed on March 23, 2020.	Fed's website
<i>CDS</i>	Credit default swap spreads on sovereign senior 5-year bond.	Datastream
<i>FedSwap</i>	Dummy variable. Equals 1 if the economy received a Federal Reserve swap-line, 0 otherwise.	Fed's website
<i>d_FOREX</i>	Rate of depreciation for the nominal exchange rates in local currency units per US dollar. End of day values.	Haver (WSJ and central bank rates)
<i>USTreasury5y</i>	Yield on 5-year Treasury bills, end of month values.	Datastream
<i>CROSS</i>	3-month Cross-currency basis, i.e., deviations from CPI	Datastream and Bloomberg
