The Performance of Emerging Markets During the Fed's Easing and Tightening Cycles: A Cross-Country Resilience Analysis Joshua Aizenman, Donghyun Park, Irfan A. Qureshi, Gazi Salah Uddin, and Jamel Saadaoui NBER Working Paper No. 32303 April 2024, Revised May 2024 JEL No. E58,F32,F36,F44,G12

ABSTRACT

We investigate the determinants of emerging markets performance during five U.S. Federal Reserve monetary tightening and easing cycles during 2004 - 2023. We study how macroeconomic and institutional conditions of an Emerging Market (EM) at the beginning of a cycle explain EM resilience during each cycle. More specifically, our baseline cross-sectional regressions examine how those conditions affect three measures of resilience, namely bilateral exchange rate against the USD, exchange rate market pressure, and country-specific Morgan Stanley Capital International index (MSCI). We then stack the five cross-sections to build a panel database to investigate potential asymmetry between tightening versus easing cycles. Our evidence indicates that macroeconomic and institutional variables are associated with EM performance, determinants of resilience differ during tightening versus easing cycles, and institutions matter more during difficult times. Our specific findings are largely consistent with economic intuition. For instance, we find that current account balance, international reserves, and inflation are all important determinants of EM resilience.

1. Introduction

The Global Financial Crisis (GFC) terminated the illusive Great Moderation (Blanchard et al. (2010)), which was followed by the U.S. Federal Reserve's alternating tightening and easing cycles shown in Figure 1. Seven years of easing induced by the GFC (2007-2014) was followed by four and a half years of tightening ('Taper Tantrum' years). Subsequently, three years of easing induced by the Covid-19 pandemic (2019-2022) led to a major tightening since February 2022, a delayed reaction to rapidly rising inflation in the US.

The VAR analysis of Rey (2015) vividly illustrated that U.S. monetary policy was a key driver of global financial cycles that affected the leverage of global banks, capital flows, and credit growth in the international financial system. Consequently, the global financial cycles propagated by U.S. shocks and policies constrained the policy options of financially integrated countries. Emerging markets in particular were exposed to 'flight to quality' at times of heightened financial instability and 'search for yields' when the U.S. Fed's massive monetary easing in response to GFC pushed the shadow Federal Funds rates toward zero (see Bernanke and Reinhart (2004), Wu and Xia (2016)).

Figure 1. Monetary cycles in the US, June 2004 - September 2023

From the perspective of most emerging markets (EMs) and developing countries, global financial cycles are exogenous shocks that test their resilience. Our paper investigates the determinants of the relative performance of emerging markets during the Fed's monetary tightening-easing cycles during the past two decades. To answer these questions, we investigate how macroeconomic conditions at the outset of each cycle influence the relative performance of emerging countries. Do *ex-ante* macroeconomic fundamentals explain why some EMs are more resilient than others during monetary cycles? Our baseline cross-sectional regressions examine how macroeconomic variables affect three measures of resilience, namely bilateral exchange rate against the USD, exchange rate market pressure (EMP) (Goldberg and Krogstrup, 2023), and country-specific

Morgan Stanley Capital International index (MSCI). We also include institutional factors as additional determinants of EM resilience.¹

We contribute to the empirical literature on EM performance in the face of U.S. monetary shocks in a number of different ways. First, our selected period allows us to better identify determinants of EM resilience because it contains big shocks such as GFC, Taper Tantrum, and Covid-19 pandemic, and sharp swings in the Fed's monetary policy. Second, we perform a comparative analysis of the determinants of EM resilience during the Fed's tightening versus easing cycles. There is no a priori reason why the determinants should be the same between the two different types of monetary policy cycles. Third, we take a deep dive into the potential link between institutions and resilience. Intuitively, sound institutions such as good governance should contribute to resilience.

Our empirical analysis yields a number of interesting findings. The current account balance is an important determinant of EMP during monetary cycles. Countries with more flexible exchange rate regimes and more developed financial markets experience lower exchange rate market pressures. Less corrupt countries experienced lower exchange rate market pressure in two out of five cycles. Countries with higher inflation experienced appreciation of their MSCI indexes in three out of five cycles. This was not the case during the GFC and Taper Tantrum. Larger current account surpluses and international reserves were associated with greater MSCI index appreciation during the three last cycles. During the GFC cycle, larger Net International Investment Positions (NIIP) were associated with better stock market performance. A combination of higher international reserves, higher current account surpluses, and larger net international investment positions helps emerging countries cope better with exchange market pressures, especially during tightening.

Financial institution development was associated with inferior performance during the first two tightening cycles - before the GFC and the Taper Tantrum. This is in line with the conjecture that financially more developed countries were more subject to capital outflows due to 'flight to safety'. Countries with less religious tensions saw their financial markets perform better during the "Taper Tantrum" cycle. Countries with fewer internal conflicts and stronger law and order suffered a more significant stock market decline during the GFC cycle. A possible interpretation is that greater trust in institutions led to a higher appreciation of stock markets during the Great Moderation. We can similarly explain why countries with better governance experienced worse stock market performance during the tightening before GFC. Countries with better democratic accountability, lower religious tensions, and stronger law and order performed better during the easing cycle triggered by the COVID-19 pandemic. We organize this paper as follows: section 2 reviews the literature. Sections 3 and 4 present the empirical methodology and results, respectively. Section 5 concludes.

2. Literature review

Previous literature has examined the impact of U.S. Federal Reserve's monetary policy on emerging market (EM) macroeconomic dynamics. Existing studies also sought to identify the characteristics that explain why the impact of such shocks varies across EMs. For example, Caldara et al. (2023) show that episodes of global

¹ There is no unique definition of resilience. We will follow Markus Brunnermeier (2022), who discuss the concept of resilience as the ability to recover from a shock. In this respect, we will investigate the performance and the 'recovery' speed (duration to peak depreciation for example) during the US monetary cycles. Besides, resilience is context-dependent. For the typical household, resilience may be more related to the speed of recovery of positive gdp growth, employment and wage level and growth, etc. For the financial sector and households with significant portfolios, upper middle class and above, the speed of portfolio loss recovery, etc.

tightening are associated with larger economic downturns, worse financial conditions, and a relatively muted decline in inflation. Ahmed et al. (2023) study the role of FX reserves in buffering the exchange rate against the US dollar during the 2021-22 Federal Reserve monetary policy tightening. They distinguish between mechanisms through which FX reserves mitigate currency depreciation. A 'balance sheet' channel implies that strong fundamentals linked with large reserves reduce currency risk even without using these reserves to intervene. Alternatively, the 'intervention' channel suggests that large reserve countries can directly intervene to protect their currencies against depreciation.² Similarly, Georgiadis et al. (2024) investigate the role in the transmission of global risk to the world economy. They show that global risk shocks appreciate the dollar, induce tighter global financial conditions, and a synchronized contraction of global economic activity. Walerych and Wesołowski (2021) find that the EM spillovers from the monetary policies of the Fed and European Central Bank are global.

In terms of country characteristics that affect the transmission of Fed shocks, the literature has primarily focused on EM monetary policy regimes (MPR). In this context, inflation targeting (IT) and exchange rate regimes receive the most attention. Aizenman et al. (2011), for instance, distinguish between group characteristics of the inflation-targeting versus non-targeting EM central banks in emerging markets. They further distinguish between commodity-exporting IT countries from other IT countries. Alvarez and De Gregorio (2014) compare the performance of IT and fixed exchange rates in countries in the context of economic resilience. Fratzscher et al. (2020) include a comprehensive set of policy-side controls, including fiscal rules, exchange rate regimes, and central bank independence (CBI). Ramos-Francia and García-Verdú (2014) examine how external monetary conditions can be a source of risks to monetary and financial stability in EMs and how their central banks should respond to such shocks. They also discuss whether EM currencies can play a more significant international role.

The broader set of country-specific characteristics that drive macroeconomic outcomes must include the economic structure. Ahmed et al. (2017) suggest that financial institutions, depth, and local currency bond markets may play an important role. Their results support the findings in Chapter 2 of the IMF (2014) World Economic Outlook (WEO), which finds that the structures of the investor base and local financial systems matter. Besides financial depth, trade and financial openness also play a major role in transmitting external shocks. The distinction between commodity importers versus exporters also matters, as Aizenman et al. (2011) discussed in the context of different policy regimes.

Finally, another branch of the literature analyzes monetary policy shocks. Hoek et al. (2022) study how US interest rates generate adverse spillovers to EMs. They undertake an event study-type approach around Federal Open Market Committee (FOMC) meetings and distinguish between two types of shock—i.e. higher rates stemming from stronger US growth versus hikes stemming from hawkish FED policy or inflationary pressures. They find the latter to be more disruptive for EMs with greater macroeconomic and financial vulnerabilities. Ahmed et al. (2017), rank EMs according to seven indicators of vulnerability, namely current account deficit, gross government debt, inflation, change in bank credit to the private sector, the ratio of external debt to exports, foreign exchange reserves, and the ratio of dollar debt net of international reserves to GDP. Ugazio and Xin (2024) study the impact of US monetary policy spillovers, in terms of both policy shock and policy news shock.

 $^{^{2}}$ Ahmed et al. (2023) focus on the role of international reserve holdings to test the validity of the buffer effect. A larger set of macroeconomic fundamentals is considered in Mishra et al. (2014) and Ahmed et al. (2017), namely: current account balance, fiscal balance, inflation, and foreign exchange reserves.

3. Methodology and data

3.1. Data

We follow Ahmed et al. (2017) to construct our database for a large sample of industrialized and emerging countries³ over the different monetary-policy cycles in the US (June 2004-September 2023). On the one hand, we build a database of explained financial variables observed at a monthly frequency, namely the bilateral exchange rate against the USD, the Exchange Rate Market Pressure (EMP) (Goldberg and Krogstrup, 2023), and the country-specific Morgan Stanley Capital International index (MSCI). On the other hand, we collect data for *exante* macroeconomic fundamentals observed at a yearly frequency from the World Bank, the IMF and the BIS (see Appendix A for the details and the complete list). Furthermore, we add a series of *ex-ante* institutional variables at a yearly frequency coming from the International Country Risk Guide database built by the PRS group.

The main *ex-ante* macroeconomic variables are the current account balance (as a percent of GDP), the reserves-to-GDP ratio, the net international investment position (as a percent of GDP), the government net lending/borrowing (as a percent of GDP); the general government gross debt (as a percent of GDP); the consumer price inflation; the fuel exports on total exports; the fuel import on total imports, the financial openness (Chinn-Ito index, see Chinn and Ito, 2006); the financial development subindexes introduced by Svirydzenka (2016); and the exchange rate stability measure developed by Aizenman et al. (2013). The *ex-ante* institutional variables are the indexes that can be found in the ICRG database. A higher score reflects a better situation regarding country risks, that is, lower risks. We have external conflicts (war, cross-border conflict), internal conflicts (civil war/coup threat, terrorism/political violence, civil disorder, foreign pressures), government stability (government cohesion, legislative strength, popular support), corruption, military in politics, and religious tensions.

The dating of monetary cycles is based on the FED fund rates and the shadow FED funds rates, as mentioned in the introduction. Consequently, the monetary cycles covered by the study are: (a) the FED tightening I: June 2004 to June 2007; (b) the FED easing I: July 2007 to May 2014; (c) the FED tightening II: June 2014 to December 2018; (d) the FED easing II: January 2019 to January 2022; and (e) the FED tightening III: February 2022 to September 2023. In fact, these cycles identify several episodes of financial stress for emerging countries. The first cycle is before the Global Financial Crisis (GFC) and corresponds to when Great Moderation was still the dominant narrative. The second cycle has begun to deal with the GFC. The third cycle is the Taper Tantrum. The fourth cycle is the pandemic cycle. Lastly, the current tightening cycle has been launched to rein in the inflation surge after the COVID-19 pandemic. The names of the variables and the acronyms used in the following tables are fully described in Appendix A.

Table 1 and Figure 1 show that the federal fund's effective rate has increased by about 4 percent in 36 months during the first monetary cycle. Despite this significant tightening, the bilateral exchange rate has shown an average appreciation. The same evolution has been observed for the EMP index, where a negative value corresponds to a weighted combination of three factors: first, an appreciation of the bilateral exchange rate; second, interventions on the FOREX market aimed at limiting the appreciation; and third, a decrease in the policy

³ The number of countries is subject to variations in the different samples due to data availability. The largest sample is a cross-section of 65 countries; see Appendix B for more details. We keep industrialized countries as a benchmark. Thus, interaction terms with EM specific dummy variables can reveal significant differences with industrialized countries.

rate. A negative value for the EMP can be interpreted as a pressure reduction. Before the Global Financial Crisis (GFC), we observed average positive stock market developments.

The second monetary cycle spans the period of the GFC. The extent of the monetary easing was considerable with the FED fund rates at above 5 percent at the beginning of the cycle. The shadow rate was around -3 percent 82 months later (see Figure 1). Episodes of financial stress drive the development of our explained financial variables during the GFC (see Table 1, gray columns). On average, the exchange rate and the EMP registered large depreciations against the US dollar (and the euro for some countries in the EMP index). Developments in the stock market are unsurprisingly adverse on average. We can note that the holding of international reserves has 'bounced back' at the end of the second monetary cycle. During financial stress episodes during the GFC, several emerging countries have used FX interventions to stabilize their exchange rates (Dominguez et al., 2012). In May 2014, the average level of holding of international reserves was 3 points higher than during the previous cycle, with a higher cross-sectional standard deviation.

IT	148	129	0.13	0.19	0	0	0.34	0.40	0	0	1	1

Note: We restricted the sample to changes in the bilateral exchange rate between -50% (appreciation) and 50% (depreciation). We use the delta log for the bilateral exchange rates and the MSCI indexes, and the delta for the EMP. We exclude countries with zero exchange rate variation during the period. Statistics for explanatory variables are only displayed for samples in which bilateral exchange rates are used. Source: authors' calculations.

In the third monetary cycle, called the "Taper Tantrum", the shadow rate increases from around -3 percent to above 2.5 percent in 54 months. During this second tightening cycle, we can observe that the average exchange rate depreciation is around 20% and the minimum value (the maximum appreciation) is below 2 percent (see Table 2). This means that virtually no currencies had appreciated against the US dollar during the Taper Tantrum.

As shown by Miranda-Agrippino and Rey (2020), US monetary policy shocks can trigger comovements in financial variables that could characterize a 'Global Financial Cycle'.⁴ Additionally, the EMP experienced lower variations than the bilateral exchange rates. The developments in the financial market were less dynamic than in the first cycle. On average, the level of international reserves is now 4 points higher compared to the end of the previous cycle.

Table 2. Descriptive statistics during the third cycle (in white) and the fourth cycle (in gray).

Note: We restricted the sample to changes in the bilateral exchange rate between -50% (appreciation) and 50% (depreciation). We use the delta log for the bilateral exchange rates and the MSCI indexes, and the delta for the EMP. We exclude countries with zero exchange rate variation during the period. Statistics for explanatory variables are only displayed for samples in which bilateral exchange rates are used. Source: authors' calculations.

The fourth monetary cycle mainly overlaps the Pandemic crisis. At the beginning of this easing cycle, the FED Fund rate was equal to 2.4 percent and below 0.1 percent 36 months later. The descriptive statistics show that the fourth monetary cycle differs from the previous economic cycles. The episodes of financial stress during this period were explained by uncertainty related to the COVID-19 pandemic. In addition, several countries implemented fiscal packages and dollar swap lines to cope with financial turmoil⁵. The variation in bilateral

⁴ As noted by Aboud et al. (2024), Chinn et al. (2024) and Goldberg and Hannaoui (2024), the international role of the US dollar has become more important after the GFC, and this trend should persist during the next years.

⁵ Aizenman et al. (2011) have shown that international reserves holding, and swap lines may be complements rather than substitutes.

exchange rates and the EMP was quite similar to that observed in the second cycle (GFC). However, the developments in the stock markets were different from during the GFC cycle, with a positive evolution on average (see Table 2).

Table 3. Descriptive statistics during the fifth cycle

Note: we restrict the sample for changes in the bilateral exchange rate between -50% (appreciation) and 50% (depreciation). We use the delta log for the bilateral exchange rates and the MSCI indexes, and the delta for the EMP. We removed countries with zero exchange rate variation during the period. Statistics for explanatory variables are only displayed for samples in which bilateral exchange rates are used. The EMP data are not available for the entire period during the fifth cycle. Source: authors' calculations.

During the last monetary cycle of our study in Table 3, the FED fund rates moved from nearly zero in February 2022 to more than 5 percent at the end of our sample in September 2023. During this monetary cycle, the bilateral exchange rate against the dollar depreciated in most economies, averaging 7 percent. Ahmed et al. (2023) showed that countries with more *ex-ante* international reserves have limited their depreciation rate⁶. The average level of international reserves is now at 28 percent. This may partially indicate that countries continuously accumulate reserves to buffer the shocks of external finance (Aizenman et al., 2024). We will come back later on this point in the empirical results section. The developments in the financial markets were not similar to those of previous cycles, with almost no variation on average of the MSCI indexes.

Choi et al. (2022) describe how the new FIMA Repo Facility has extended access to dollar liquidity during the pandemic. ⁶ Coulibaly et al. (2024) confirm the buffer effect of international reserve holdings on the exchange rate and public debt for 54 African countries. Exposure to the 'Belt and Road initiative' will be explored when more comprehensive data will be available on public debt for African economies. Recently, China has become "an international lender of last resort" as shown by Horn et al. (2023).

3.2. Methodology

We will use first cross-sectional regressions where the explanatory variables would be fundamentals observed before the events, and the left-hand variable would be the performance of the financial variable of interest over the monetary cycle:

$$\Delta FinVar = c + \sum_{j} \beta_{j} X_{i,j} + \varepsilon_{i}$$

where each *i* denotes a particular country. We use multiple financial indicators to build the dependent variable in alternative specifications, with the change in each indicator represented by Δ measuring financial performance during the monetary cycle. $X_{i,j}$ are a set of explanatory variables, *j* specific to country *i* measured in **the year prior to the monetary cycle**, β_j are parameters to be estimated, and ε_i are error terms. Note that the cross-section observations in each regression are the countries, and a separate regression is run for each dependent variable and each subset of explanatory variables *j*.

Following Ahmed, Coulibaly, and Zlate (2017), we analyze economic performance on a cross-sectional basis and include the **initial macroeconomic and institutional conditions** at the beginning of each cycle. Possible candidates for the initial conditions include stock variables, including the ratio of initial international reserves to GDP, public debt in local currency / foreign currency as a percentage of GDP, private debt as a percentage of GDP, and other variables.

In the spirit of Alvarez and De Gregorio (2014), we will examine the changing patterns of resilience, comparing the performance of IT and fixed exchange rates in countries⁷. Examining the heterogeneity of the performance of emerging countries during these monetary cycles can help policymakers build policy space to cope with future cycles. We will identify the asymmetries during monetary easing and monetary tightening. These asymmetries may provide useful information to policy-makers about excessive leverage during monetary easing, since monetary easing associated with underregulated leverage growth may increase macroeconomic vulnerability in the next cycle.

4. Empirical results

4.1. Baseline regressions

Tables 4 to 9 present the results of the cross-sectional regression for the bilateral exchange rate variation, the variation of the EMP indexes and the MSCI indexes variation, respectively, during the different monetary cycles⁸. As explained in Subsection 3.2, main our objective is to explain the difference in the cross-country performance and resilience during monetary cycles, and especially tightenings, according to *ex-ante* macroeconomic fundamentals and *ex-ante* institutional variables. We may briefly recall identifying several key determinants of economic performance, and resilience will help us to provide sound policy recommendations to

⁷ A natural extension will be to control for crisis dummies, as in Leaven and Valencia (2020), and for the history of crises (possibly by discounting past crises, in line with the diminishing effects of more distant crises relative to the more recent crises).

⁸ The pairwise correlation between variables is below 50% in almost all cases. In all the regressions, the null hypothesis of normality for the residuals is not rejected at conventional significance levels.

cope with international financial spillovers. In Table 4, we have the full specification of the macroeconomic and institutional determinants of economic performance. Furthermore, we use a stepwise backward stepwise selection with a threshold value of 20% for the p-value in Table 5. We can observe that the explanatory power ranges from 41% to 68% according to the R-squared values throughout Tables 4 and 5.

We can note that the negative coefficient on the international reserves holding indicates that the buffer effect of international reserves holding is confirmed for three cycles out of five. This finding generalizes the results of Ahmed et al. (2023) and is in line with those of Aizenman et al. (2024). The holding of international reserves has stabilization properties on the exchange rate through both the balance sheet channel and the intervention channel. Indeed, Ahmed et al. (2023) show that currency interventions were associated with less exchange depreciation when the *ex-ante* stock of high reserve was high during the fifth cycle. Furthermore, countries with higher values for *ex-ante* consumer price inflation have experienced larger depreciation rates during three cycles out of five. In light of purchasing power parity (PPP) theory, these last results may reveal that the exchange rate depreciation follows the price differentials over the medium run.

According to Rose (2020), the success of the inflation-targeting regime was explained by its performance in terms of resilience to external finance shocks and, especially in terms of limiting the risk of currency crisis. As Rose recalled, a country cannot be forced to quit an inflation-targeting regime contrary to a fixed-exchange-rate regime. As mentioned by Aizenman et al. (2011), emerging countries have followed a mixed strategy for their nominal anchor. However, the policy response to exchange rate depreciations to limit imported inflation was more constrained for countries without an inflation-targeting regime. Consistent with these results, before the GFCinduced monetary cycle, being an inflation targeter before entering the cycle was associated with lower exchange rate depreciation.

Two points can be mentioned to assess the respective influence of inflation targeting during these monetary cycles. The first one is the distinction between *de jure* inflation targeters and *de facto* inflation targeters. Indeed, this distinction may be crucial as some countries declare to be inflation targeters, but constantly miss the inflation target, Turkey being a prime example. The second point related to the performance of inflation targeters is the distinction between 'young' and 'old' inflation targeters. One possible conjecture would be that the dynamics gains in terms of resilience increase with time and with the credibility of the inflation-targeting regime ('de jure' versus 'de facto').

In light of this possible complementarity between inflation-targeting regimes and fixed-exchange rate regimes (Aizenman et al., 2011), we can note that less flexible exchange rate regimes played an important role during the Taper tantrum and the Pandemic monetary cycles. Indeed, we found that the exchange rate depreciation was more limited in countries with higher *ex-ante* exchange rate stability⁹. This empirical evidence shows that the relative merits of inflation-targeting and flexible exchange rate regimes vary over time. The stabilizing properties of these different regimes may evolve over the different monetary cycles. We may also suspect the presence of non-linearities.

Tables 6 and 7 show that the explanatory power for EMP regression ranges from 30 percent to 80 percent¹⁰. The EMP index considers the interdependence between bilateral exchange rates, foreign exchange intervention, and policy rate changes. As fully described by Goldberg and Krogstrup (2022), the EMP index can be seen as a

⁹ The data for the Exchange Rate Stability are not available during the fifth cycle.

¹⁰ The data for the EMP indexes are not available during the fifth cycle.

comprehensive exchange rate policy index. The weights for bilateral exchange rates, foreign exchange intervention (FXI), and policy rate changes are framed in a model of supply and demand for foreign currency: "Any given excess supply or demand for a currency - an international capital flow pressure - can be offset by an equivalent amount of FXI, or by an endogenous exchange rate movement or change in the domestic monetary policy rate sufficient to generate an offsetting private balance of payments flow" (Goldberg and Krogstrup, 2022). Consequently, the EMP index can capture dimensions of international financial spillovers other than simple bilateral exchange rates.

Table 4. Cross-sectional regressions for bilateral exchange rate variation

Note: *** p<0.01, ** p<0.05, * p<0.1. Robust standard errors are in parentheses. Data for the index of exchange rate stability (ers) are not available for the fifth cycle. Bold indicates a significance level below 5%. Source: authors' calculations.

We find that the current account balance is now an important determinant of EMP variations during monetary cycles. An *ex-ante* current account surplus can offer more room for maneuvering intervention during the monetary cycle, especially during tightening, to cope with flight-to-quality movements. We observe that countries with less flexible exchange rate regimes and more developed financial markets experience less exchange rate market pressures. In light of the previous discussion on the relative merits of inflation-targeting regimes and less flexible exchange rate regimes, we found that exchange rate stability is associated with fewer exchange rate pressures in three cycles out of five.¹¹

Table 7. Cross-sectional regressions for the EMP variation - backward stepwise selection

RMSE1.8432.1402.1292.738Note: *** p<0.01, ** p<0.05, * p<0.1. Robust standard errors are in parentheses. Data for the EMP indexes are not available during the fifth cycle. We
use a backward stepwise selection procedure for the variables. Variables with p-values above 20% are sequentially removed from the model from the
highest to the lowest p-value. Bold indicates a significance level below 5%. Source: authors' calculations.

For the institutional variables, countries with higher levels of corruption rating (less corruption) experience less exchange rate market pressure in two cycles out of five. The difference between financial institution development and financial market development can provide interesting insights. More developed financial markets help to cope with pressures. Besides, financial institution development is associated with higher pressures. The influence of institutional variables depends on the monetary cycle. There is a larger, significant positive association during the GFC. This may reveal that institutional variables may play a more important role during large recessions and episodes of acute financial stress¹².

In Tables 8 and 9, we can see that countries with higher levels of CPI inflation have experienced an appreciation of their MSCI indexes in three cycles out of five. This was not the case during the GFC during the Taper tantrum. For countries with larger surpluses in the current account balance and *ex-ante* larger holdings of international reserves, the MSCI indexes have appreciated during the three last cycles. During the second cycle, the GFC cycle, large NIIPs were associated with better performance of their stock markets. In fact, a combination of international reserves, current account surpluses, or positive net international investment positions can help emerging countries cope with stock market pressures, especially during tightening episodes.

The development of financial institutions was associated with inferior performance and resilience during the first two tightenings, namely, before the GFC and the 'Taper Tantrum'. We can conjecture that countries with a higher degree of development in their financial institutions may be subject to a higher movement of mistrust in the financial markets, especially emerging countries that have an intermediate level in development of their financial institution's role was vital during the GFC and the "Taper Tantrum" cycle. In addition to the financial institution variable, the institutional variables had some significance. For example, in countries with less religious tensions (i.e., a higher score for the variable relations), their financial markets performed better than other countries during the "Taper Tantrum" cycle.

Furthermore, countries with less internal conflict (i.e., a better score in the intconf variable) and a better score in terms of 'Law and Order' have experienced a more significant decline in their stock market during the GFC cycle¹³. We can also mention that countries with better governance stability have experienced worsened performance on the stock markets over the first cycle, the tightening before the GFC. Finally, countries with better democratic accountability, less religious tensions,¹⁴ and a better score in the variable 'law order' have experienced better performance during the easing cycle induced by the COVID-19 pandemic.

Finally, it could be useful to provide an overview of the results discovered in our research as we run several cross-country regressions for three macro-financial variables. The general findings are as follows in the models with backward stepwise selection tables in Tables 5, 7, and 9. First, cross-country heterogeneity in the *exante* macroeconomic fundamentals and institutional variables has some explanatory power in explaining the differences in the performance and resilience of a large cross-section of emerging countries during the different US monetary cycles. Especially, the relative merits of inflation-targeting regimes and less flexible exchange rate regimes vary over time.

Second, these determinants are asymmetric during tightenings and easings, which may indicate that during tightenings, especially more recent tightenings due to dollar dominance, the resilience of countries is revealed.

¹² This may be illustrated by the famous Warren buffet's quote: "A rising tide floats all boats..... only when the tide goes out do you discover who's been swimming naked." The role of institution quality may be hidden during monetary easing. Large episodes of financial and economic stress may reveal the importance of good institutions.

¹³ A possible interpretation is that they trusted their institutions more, thereby experiencing a higher appreciation of their stock markets during the great moderation..

¹⁴ At the 10 percent level.

That being said, the influence of holdings of international reserves, CPI inflation, and current balance are welldefined during several monetary cycles for our three explained variables.

Third, the significance of *ex-ante* institutional variables increases during the GFC and the 'Taper Tantrum' monetary cycles, which may indicate that the benefits of having good institutions can only be revealed during difficult times (when the tide is low). This potential asymmetry may be related to the real-time reaction of policymakers in the face of unexpected events. This 'de facto' quality of institutions may be the yardstick on which resilience and performance should be evaluated.

Source: authors' calculations.

For the sake of completeness, we compute two other measures of resilience in Tables 10 to 13. First, we compute the number of months required to reach peak depreciation in Tables 10 and 11. Second, we compute the number of months required to reach the lowest point in the equity MSCI index in Tables 12 and 13. Interestingly, we can note that being an inflation targeter is associated with a reduction of the number of months necessary to reach peak depreciation.

Table 13. Cross-sectional regressions for the time to lowest point in equity MSCI - indexes backward stepwise selection

Note: *** p < 0.01, ** p < 0.05, * p < 0.1. Robust standard errors are in parentheses. We use a backward stepwise selection procedure for the variables. The variables with p-values above 20% are sequentially removed from the model starting from the highest to the lowest p-value. Bold indicates a significance level below 5%. Source: authors' calculations.

4.2. Panel data regressions

After exploring cross-sectional regressions, we stack the cross-sections to build an unbalanced panel database where the time dimension will be our five cycles, so T = 5 or 4 (depending on data availability). We preserve the chronological structure of the data as the US monetary cycles are observed at the same time for all the countries. Thus, we explore the potential asymmetries between monetary cycles. Thanks to dummy variables for tightening and easing episodes. Figures 2 and 3 present graphical evidence showing that the benefit of having a better score in the government stability variable only appears during tightening by limiting exchange rate depreciation and providing an expansion of the stock market.

Figure 2. Asymmetries during tightening cycles for the bilateral exchange rate

Note: with the data sample of Appendix C for the 5 cycles. The score of Government Stability is observed one year before each cycle. Source: authors' calculations.

Tables 14 to 16 provide empirical evidence that confirms our preliminary graphical evidence. The benefit of having better government stability only appears during bad times for the exchange rate and the stock market indexes. For the exchange rate market pressure index, the financial institutions variable is associated with an increase of pressures and democratic accountability is associated with a reduction of pressures, in line with the cross-sectional regressions.¹⁵

¹⁵ In Appendix D and E, we provide panel evidence for the 5 cycles in the case of the bilateral exchange rate variations and the MSCI variations during the cycles.

Table 16. Panel evidence for MSCI indexes

Note: *** p < 0.01, ** p < 0.05, * p < 0.1. Robust standard errors are in parentheses. We use a backward stepwise selection procedure for the variables. The variables with p-values above 20% are sequentially removed from the model starting from the highest to the lowest p-value. Bold indicates a significance level below 5%. Only the four first cycles are included, as we use the ers variable in the backward stepwise selection procedure. The dummies 'tight' and 'easy' refer to tightening and easing cycles, respectively. Source: authors' calculations.

Note: with the data sample of Appendix D for the 5 cycles. The score of Government Stability is observed one year before each cycle. Source: authors' calculations.

4.3. Robustness checks

In Appendix E, we present several robustness check results where we pooled all the cycles (column 1), pooled the tightening cycles (column 2), pooled the easing cycles (column 3), assumed a homogeneous interaction between tightening cycles and the main explanatory variables (column 4), and assumed a heterogeneous interaction between tightening cycles and the main explanatory variables (column 5) for the bilateral exchange rate in Table E1, and for the MSCI indexes in Table E2. Overall, the results indicate robustness, especially for the asymmetries between government stability during the tightening and easing cycles. Tables E1 and E2 provide us with some insight into the importance of building an institutional framework that helps to enhance resilience and performance during bad times. The initial cross-country position of government stability explains the cross-country performance and resilience of countries during the next monetary cycles. These pieces of evidence show that even if building relevant institutions is difficult and takes time, this may provide long-run benefits and maintain the economy on a sustainable path. Appendix Figures A1 and A2 present panel quantile evidence that supports the results of Table F1 and F2. Higher government stability provides better resilience to depreciation for higher quantiles of the depreciation rate. In addition, better government stability allows for better performance on equity markets for lower quantiles of the MSCI indexes.

5. Conclusion

The share of the U.S. in global output has steadily declined in recent years. The relative decline of the U.S. in the world economy mirrors the relative decline of advanced economies as a whole and the corresponding rise of emerging markets spearheaded by China. However, despite the relative decline of the U.S. in the real economy,

the U.S. dollar still reigns supreme. The dollar still dominates international trade and financial transactions, foreign exchange reserves of central banks, and the denomination of oil and other commodities. Furthermore, the dominance looks set to continue into the foreseeable future in light of the increase in global uncertainty in the post-COVID-19 world and the enduring safe haven currency status of the dollar. The unchallenged supremacy of the dollar, combined with the world's largest and most liquid financial markets, means that swings in the U.S. Federal Reserve's monetary policy have an outsized impact on global financial markets. Emerging markets are especially vulnerable to the Fed's tightening and easing cycles. However, some emerging markets are more resilient than others. The natural question that arises is, why?

Our empirical analysis of the determinants of emerging-market resilience in response to the Fed's policy delved into five alternating tightening and easing cycles between 2004 and 2023. This period is ideal for investigating our research question because it contains big shocks such as the global financial crisis, the Taper Tantrum, and the COVID-19 pandemic, which induced sharp swings in U.S. monetary policy. Cross-country regressions explored the link between *ex-ante* macroeconomic and institutional variables and three measures of resilience, namely bilateral exchange rate against the USD, exchange rate market pressure (EMP) (Goldberg and Krogstrup, 2023), and country-specific Morgan Stanley Capital International index (MSCI). At a broader level, our analysis confirms that *ex-ante* macroeconomic and institutional variables do matter, determinants of resilience differ during U.S. tightening versus easing, and institutional variables gain greater significance during downturns.

Our evidence sheds new light on the relative role of various macroeconomic and institutional variables in explaining the resilience of emerging markets in response to the Fed's tightening and easing cycles. A key result of our paper is the asymmetric importance of institutional variables, where these variables gain much greater significance during downturns. This result is in line with the paradox of regulation: Effective regulator effort, while helping avoid a crisis, may be confused as a signal that the environment is less risky, reducing the posterior probability of the crisis, and eroding the political support for costly regulation. This may test the independence of central banks, and their ability to withstand this pressure. A recent example of these dynamics is the relaxation of the Dodd-Frank tightening banks' supervision due to political pressure in 2018, just 10 years after the GFC explained the Silicon Valley bank and other banks' 2023 collapses. This concern remains the enduring challenge of regulatory quality, testing all central banks' time consistency and independence, especially at a time of growing fiscal dominance pressures.

Emerging-market policymakers can infer some policy implications from our specific empirical findings. For instance, we find that international reserves, current account balance, and inflation are all important determinants of performance in response to U.S. monetary policy swings. This reinforces the conventional wisdom that strong fundamentals protect emerging markets. Our study contributes to the literature on emerging-market resilience to U.S. monetary policy by analyzing the behavior of three measures of resilience over a period that witnessed extended cycles of both tightening and easing. Another contribution is our comparative analysis of emerging-market response to tightening versus easing cycles. Finally, our paper suggests several future research directions. For one, we can explore the performance of the emerging-market real economy to the tightening and easing cycles of the U.S. Fed. Another idea is to replicate our exercise for the European Central Bank or People's Bank of China. And yet another idea is to explore why some emerging-market central banks follow the Fed's lead more than others. Besides, we expect that the interaction of geopolitical interests with strong macroeconomic fundamentals will have more influence in recent monetary cycles. Does geopolitical proximity to China hinder the buffer effect of strong fundamentals during recent monetary cycles? These are just a few examples of related future research.

Table F2. Panel evidence for the MSCI indexes during the five cycles

RMSE39.1835.0538.3636.4131.12Note: *** p<0.01, ** p<0.05, * p<0.1. Robust standard errors are in parentheses. We use a backward stepwise selection procedure for the variables.
The variables with p-values above 20% are sequentially removed from the model starting from the highest to the lowest p-value. Bold indicates a
significance level below 5%. The dummies 'tight' and 'easy' refer to tightening and easing cycles, respectively. Source: authors' calculations.

Appendix Figures

Note: the dotted lines correspond to the OLS estimation for each coefficient. The blue line and the shaded area indicates the percentile estimates. We use the model in column 5 of Table E1. The variables with the '_tight' term indicates interaction tems with the tightening cycles dummy and the corresponding ex-ante macroeconomic variable. Source: authors' calculations.

Quantile regressions - MSCI Indexes

Note: the dotted lines correspond to the OLS estimation for each coefficient. The blue line and the shaded area indicates the percentile estimates. We use the model in column 5 of Table F1. The variables with the '_tight' term indicates interaction tems with the tightening cycles dummy and the corresponding ex-ante macroeconomic variable. Source: authors' calculations.
